

and

$$x_3(n) = x_1(n - 2)$$

Thus from (3.2.5) we obtain

$$X_2(z) = z^2 X_1(z) = z^2 + 2 + 5 + 7z^{-1} + z^{-3}$$

and

$$X_3(z) = z^{-2} X_1(z) = z^{-2} + 2z^{-3} + 5z^{-4} + 7z^{-5} + z^{-7}$$

Note that because of the multiplication by z^2 , the **ROC** of $X_2(z)$ does not include the point $z = \infty$, even if it is contained in the **ROC** of $X_1(z)$.

Example 3.2.3 provides additional insight in understanding the meaning of the shifting property. Indeed, if we recall that the coefficient of z^{-n} is the sample value at time n , it is immediately seen that delaying a signal by k ($k > 0$) samples [i.e., $x(n) \rightarrow x(n - k)$] corresponds to multiplying all terms of the z -transform by z^{-k} . The coefficient of z^{-n} becomes the coefficient of $z^{-(n+k)}$.

Example 3.2.4

Determine the transform of the signal

$$x(n) = \begin{cases} 1, & 0 \leq n \leq N-1 \\ 0, & \text{elsewhere} \end{cases} \quad (3.2.6)$$

Solution We can determine the z -transform of this signal by using the definition (3.1.1). Indeed,

$$X(z) = \sum_{n=0}^{N-1} 1 \cdot z^{-n} = 1 + z^{-1} + \cdots + z^{-(N-1)} = \begin{cases} N, & \text{if } z = 1 \\ \frac{1 - z^{-N}}{1 - z^{-1}}, & \text{if } z \neq 1 \end{cases} \quad (3.2.7)$$

Since $x(n)$ has finite duration, its **ROC** is the entire z -plane, except $z = 0$.

Let us also derive this transform by using the linearity and time shifting properties. Note that $x(n)$ can be expressed in terms of two unit step signals

$$x(n) = u(n) - u(n - N)$$

By using (3.2.1) and (3.2.5) we have

$$X(z) = Z\{u(n)\} - Z\{u(n - N)\} = (1 - z^{-N})Z\{u(n)\} \quad (3.2.8)$$

However, from (3.1.8) we have

$$Z\{u(n)\} = \frac{1}{1 - z^{-1}} \quad \text{ROC: } |z| > 1$$

which, when combined with (3.2.8), leads to (3.2.7).

Example 3.2.4 helps to clarify a very important issue regarding the ROC of the combination of several z -transforms. If the linear combination of several signals has finite duration, the ROC of its z -transform is exclusively dictated by the finite-duration nature of this signal, not by the ROC of the individual transforms.

Scaling in the z -domain. If

$$x(n) \xleftrightarrow{z} X(z) \quad \text{ROC: } r_1 < |z| < r_2$$

then

$$a^n x(n) \longleftrightarrow X(a^{-1}z) \quad \text{ROC: } |a|r_1 < |z| < |a|r_2 \quad (3.2.9)$$

for any constant a , real or complex.

Proof: From the definition (3.1.1)

$$\begin{aligned} Z\{a^n x(n)\} &= \sum_{n=-\infty}^{\infty} a^n x(n) z^{-n} = \sum_{n=-\infty}^{\infty} x(n) (a^{-1}z)^{-n} \\ &= X(a^{-1}z) \end{aligned}$$

Since the ROC of $X(z)$ is $r_1 < |z| < r_2$, the ROC of $X(a^{-1}z)$ is

$$r_1 < |a^{-1}z| < r_2$$

or

$$|a|r_1 < |z| < |a|r_2$$

To better understand the meaning and implications of the scaling property, we express a and z in polar form as $a = r_0 e^{j\omega_0}$, $z = r e^{j\omega}$, and we introduce a new complex variable $w = a^{-1}z$. Thus $Z\{x(n)\} = X(z)$ and $Z\{a^n x(n)\} = X(w)$. It can easily be seen that

$$w = a^{-1}z = \left(\frac{1}{r_0}r\right) e^{j(\omega - \omega_0)}$$

This change of variables results in either shrinking (if $r_0 > 1$) or expanding (if $r_0 < 1$) the z -plane in combination with a rotation (if $\omega_0 \neq 2k\pi$) of the z -plane (see Fig. 3.6). This explains why we have a change in the ROC of the new transform where $|a| < 1$. The case $|a| = 1$, that is, $a = e^{j\omega_0}$ is of special interest because it corresponds only to rotation of the z -plane.

Example 3.25

Determine the z -transforms of the signals

- (a) $x(n) = a^n (\cos \omega_0 n) u(n)$
 (b) $x(n) = a^n (\sin \omega_0 n) u(n)$

Figure 3.6 Mapping of the z -plane to the w -plane via the transformation $w = a^{-1}z$, $a = r_0 e^{j\omega_0}$.

Solution

(a) From (3.2.3) and (3.2.9) we easily obtain

$$a^n (\cos \omega_0 n) u(n) \xleftrightarrow{z} \frac{1 - az^{-1} \cos \omega_0}{1 - 2az^{-1} \cos \omega_0 + a^2 z^{-2}} \quad |z| > |a| \quad (3.2.10)$$

(b) Similarly, (3.2.4) and (3.2.9) yield

$$a^n (\sin \omega_0 n) u(n) \xleftrightarrow{z} \frac{az^{-1} \sin \omega_0}{1 - 2az^{-1} \cos \omega_0 + a^2 z^{-2}} \quad |z| > |a| \quad (3.2.11)$$

Time reversal. If

$$x(n) \xleftrightarrow{z} X(z) \quad \text{ROC: } r_1 < |z| < r_2$$

then

$$x(-n) \xleftrightarrow{z} X(z^{-1}) \quad \text{ROC: } \frac{1}{r_2} < |z| < \frac{1}{r_1} \quad (3.2.12)$$

Proof. From the definition (3.11), we have

$$Z\{x(-n)\} = \sum_{n=-\infty}^{\infty} x(-n)z^{-n} = \sum_{l=-\infty}^{\infty} x(l)(z^{-1})^{-l} = X(z^{-1})$$

where the change of variable $l = -n$ is made. The ROC of $X(z^{-1})$ is

$$r_1 < |z^{-1}| < r_2 \quad \text{or equivalently} \quad \frac{1}{r_2} < |z| < \frac{1}{r_1}$$

Note that the ROC for $x(n)$ is the inverse of that for $x(-n)$. This means that if z_0 belongs to the ROC of $x(n)$, then $1/z_0$ is in the ROC for $x(-n)$.

An intuitive proof of (3.2.12) is the following. When we fold a signal, the coefficient of z^{-n} becomes the coefficient of z^n . Thus, folding a signal is equivalent to replacing z by z^{-1} in the z -transform formula. In other words, reflection in the time domain corresponds to inversion in the z -domain.

Example 3.2.6

Determine the z -transform of the signal

$$x(n) = u(-n)$$

Solution It is known from (3.1.8) that

$$u(n) \xleftrightarrow{z} \frac{1}{1 - z^{-1}} \quad \text{ROC: } |z| > 1$$

By using (3.2.12), we easily obtain

$$u(-n) \xleftrightarrow{z} \frac{1}{1 - z} \quad \text{ROC: } |z| < 1 \quad (3.2.13)$$

Differentiation in the z -domain. If

$$x(n) \xleftrightarrow{z} X(z)$$

then

$$nx(n) \xleftrightarrow{z} -z \frac{dX(z)}{dz} \quad (3.2.14)$$

Proof. By differentiating both sides of (3.1.1), we have

$$\begin{aligned} \frac{dX(z)}{dz} &= \sum_{n=-\infty}^{\infty} x(n)(-n)z^{-n-1} = -z^{-1} \sum_{n=-\infty}^{\infty} [nx(n)]z^{-n} \\ &= -z^{-1} Z\{nx(n)\} \end{aligned}$$

Note that both transforms have the same ROC.

Example 3.2.7

Determine the z-transform of the signal

$$x(n) = na^n u(n)$$

Solution The signal $x(n)$ can be expressed as $nx_1(n)$, where $x_1(n) = a^n u(n)$. From (3.2.2) we have that

$$x_1(n) = a^n u(n) \xleftrightarrow{z} X_1(z) = \frac{1}{1 - az^{-1}} \quad \text{ROC: } |z| > |a|$$

Thus, by using (3.2.14), we obtain

$$na^n u(n) \xleftrightarrow{z} X(z) = -z \frac{dX_1(z)}{dz} = \frac{az^{-1}}{(1 - az^{-1})^2} \quad \text{ROC: } |z| > |a| \quad (3.2.15)$$

If we set $a = 1$ in (3.2.15), we find the z-transform of the unit ramp signal

$$nu(n) \xleftrightarrow{z} \frac{-1}{(1 - z^{-1})^2} \quad \text{ROC: } |z| > 1 \quad (3.2.16)$$

Example 3.2.8

Determine the signal $x(n]$ whose z-transform is given by

$$X(z) = \log(1 + az^{-1}) \quad |z| > |a|$$

Solution By taking the first derivative of $X(z)$, we obtain

$$\frac{dX(z)}{dz} = \frac{-az^{-2}}{1 + az^{-1}}$$

Thus

$$-z \frac{dX(z)}{dz} = az^{-1} \left[\frac{1}{1 - (-a)z^{-1}} \right] \quad |z| > |a|$$

The inverse z-transform of the term in brackets is $(-a)^n$. The multiplication by z^{-1} implies a time delay by one sample (time shifting property), which results in $(-a)^{n-1}u(n-1)$. Finally, from the differentiation property we have

$$nx(n) = a(-a)^{n-1}u(n-1)$$

or

$$x(n) = (-1)^{n+1} \frac{a^n}{n} u(n-1)$$

Convolution of two sequences. If

$$x_1(n) \xleftrightarrow{z} X_1(z)$$

$$x_2(n) \xleftrightarrow{z} X_2(z)$$

then

$$x(n) = x_1(n) * x_2(n) \xleftrightarrow{z} X(z) = X_1(z)X_2(z) \quad (3.2.17)$$

The ROC of $X(z)$ is, at least, the intersection of that for $X_1(z)$ and $X_2(z)$.**Proof** The convolution of $x_1(n)$ and $x_2(n)$ is defined as

$$x(n) = \sum_{k=-\infty}^{\infty} x_1(k)x_2(n-k)$$

The z-transform of $x(n)$ is

$$X(z) = \sum_{n=-\infty}^{\infty} x(n)z^{-n} = \sum_{n=-\infty}^{\infty} \left[\sum_{k=-\infty}^{\infty} x_1(k)x_2(n-k) \right] z^{-n}$$

Upon interchanging the order of the summations and applying the time-shifting property in (3.2.5), we obtain

$$\begin{aligned} X(z) &= \sum_{k=-\infty}^{\infty} x_1(k) \left[\sum_{n=-\infty}^{\infty} x_2(n-k)z^{-n} \right] \\ &= X_2(z) \sum_{k=-\infty}^{\infty} x_1(k)z^{-k} = X_2(z)X_1(z) \end{aligned}$$

Example 329Compute the convolution $x(n)$ of the signals

$$x_1(n) = \{1, -2, 1\}$$

$$x_2(n) = \begin{cases} 1, & 0 \leq n \leq 5 \\ 0, & \text{elsewhere} \end{cases}$$

Solution From (3.1.1), we have

$$X_1(z) = 1 - 2z^{-1} + z^{-2}$$

$$X_2(z) = 1 + z^{-1} + z^{-2} + z^{-3} + z^{-4} + z^{-5}$$

According to (3.2.17), we carry out the multiplication of $X_1(z)$ and $X_2(z)$. *Thus*

$$X(z) = X_1(z)X_2(z) = 1 - z^{-1} - z^{-6} + z^{-7}$$

Hence

$$x(n) = \{1, -1, 0, 0, 0, 0, -1, 1\}$$

↑

Sec. 3.2 Properties of the z-Transform

The same result can also be obtained by noting that

$$X_1(z) = (1 - z^{-1})^2$$

$$X_2(z) = \frac{1 - z^{-6}}{1 - z^{-1}}$$

Then

$$X(z) = (1 - z^{-1})(1 - z^{-6}) = 1 - z^{-1} - z^{-6} + z^{-7}$$

The reader is encouraged to obtain the same result explicitly by using the convolution summation formula (time-domain approach).

The convolution property is one of the most powerful properties of the z-transform because it converts the convolution of two signals (time domain) to multiplication of their transforms. Computation of the convolution of two signals, using the z-transform, requires the following steps:

1. Compute the z-transforms of the signals to be convolved.

$$X_1(z) = Z\{x_1(n)\}$$

(time domain $\xrightarrow{\quad}$ z-domain)

$$X_2(z) = Z\{x_2(n)\}$$

2. Multiply the two z-transforms.

$$X(z) = X_1(z)X_2(z) \quad (\text{z-domain})$$

3. Find the inverse z-transform of $X(z)$.

$$x(n) = Z^{-1}\{X(z)\} \quad (\text{z-domain} \longrightarrow \text{time domain})$$

This procedure is, in many cases, computationally easier than the direct evaluation of the convolution summation.

Correlation of two sequences. If

$$x_1(n) \xrightarrow{Z} X_1(z)$$

$$x_2(n) \xrightarrow{Z} X_2(z)$$

then

$$r_{x_1x_2}(l) = \sum_{n=-\infty}^{\infty} x_1(n)x_2(n-l) \xrightarrow{Z} R_{x_1x_2}(z) = X_1(z)X_2(z^{-1}) \quad (3.2.18)$$

Proof: We recall that

$$r_{x_1x_2}(l) = x_1(l) * x_2(-l)$$

Using the convolution and time-reversal properties, we easily obtain

$$R_{x_1 x_2}(z) = Z\{x_1(l)\}Z\{x_2(-l)\} = X_1(z)X_2(z^{-1})$$

The ROC of $R_{x_1 x_2}(z)$ is at least the intersection of that for $X_1(z)$ and $X_2(z^{-1})$.

As in the case of convolution, the crosscorrelation of two signals is more easily done via polynomial multiplication according to (3.2.18) and then inverse transforming the result.

Example 3.2.10

Determine the autocorrelation sequence of the signal

$$x(n) = a^n u(n), \quad -1 < a < 1$$

Solution Since the autocorrelation sequence of a signal is its correlation with itself, (3.2.18) gives

$$R_{xx}(z) = Z\{r_{xx}(l)\} = X(z)X(z^{-1})$$

From (3.2.2) we have

$$X(z) = \frac{1}{1 - az^{-1}} \quad \text{ROC: } |z| > |a| \quad (\text{causal signal})$$

and by using (3.2.15), we obtain

$$X(z^{-1}) = \frac{1}{1 - a:} \quad \text{ROC: } |z| < \frac{1}{|a|} \quad (\text{anticausal signal})$$

Thus

$$R_{xx}(z) = \frac{1}{1 - az^{-1}} \frac{1}{1 - a:} = \frac{1}{1 - a(: + z^{-1}) + a^2} \quad \text{ROC: } |a| < |z| < \frac{1}{|a|}$$

Since the ROC of $R_{xx}(z)$ is a ring, $r_{xx}(l)$ is a two-sided signal, even if $x(n)$ is causal.

To obtain $r_{xx}(l)$, we observe that the z -transform of the sequence in Example 3.1.5 with $b = 1/a$ is simply $(1 - a^2)R_{xx}(z)$. Hence it follows that

$$r_{xx}(l) = \frac{1}{1 - a^2} a^{|l|} \quad -\infty < l < \infty$$

The reader is encouraged to compare this approach with the time-domain solution of the same problem given in Section 2.6.

Multiplication of two sequences. If

$$x_1(n) \xleftrightarrow{z} X_1(z)$$

$$x_2(n) \xleftrightarrow{z} X_2(z)$$

then

$$x(n) = x_1(n)x_2(n) \xleftrightarrow{z} X(z) = \frac{1}{2\pi j} \oint_C X_1(v)X_2\left(\frac{z}{v}\right)v^{-1}dv \quad (3.2.19)$$

where C is a closed contour that encloses the origin and lies within the region of convergence common to both $X_1(v)$ and $X_2(1/v)$.

Sec. 3.2 Properties of the z-Transform

Proof. The z-transform of $x_3(n)$ is

$$X(z) = \sum_{n=-\infty}^{\infty} x(n)z^{-n} = \sum_{n=-\infty}^{\infty} x_1(n)x_2(n)z^{-n}$$

Let us substitute the inverse transform

$$x_1(n) = \frac{1}{2\pi j} \oint_{\mathcal{C}} X_1(v)v^{n-1} dv$$

for $x_1(n)$ in the z-transform $X(z)$ and interchange the order of summation and integration. **Thus** we obtain

$$X(z) = \frac{1}{2\pi j} \oint_{\mathcal{C}} X_1(v) \left[\sum_{n=-\infty}^{\infty} x_2(n) \left(\frac{z}{v}\right)^{-n} \right] v^{-1} dv$$

The sum in the brackets is simply the transform $X_2(z)$ evaluated at z/v . Therefore,

$$X(z) = \frac{1}{2\pi j} \oint_{\mathcal{C}} X_1(v) X_2\left(\frac{z}{v}\right) v^{-1} dv$$

which is the desired result.

To obtain the ROC of $X(z)$ we note that if $X_1(v)$ converges for $r_{1l} < |v| < r_{1u}$ and $X_2(z)$ converges for $r_{2l} < |z| < r_{2u}$, then the ROC of $X_2(z/v)$ is

$$r_{2l} < \left| \frac{z}{v} \right| < r_{2u}$$

Hence the ROC for $X(z)$ is at least

$$r_{1l}r_{2l} < |z| < r_{1u}r_{2u} \quad (3.2.20)$$

Although this property will not be used immediately, it will prove useful later, especially in our treatment of filter design based on the window technique, where we multiply the impulse response of an IIR system by a finite-duration "window" which serves to truncate the impulse response of the IIR system.

For complex-valued sequences $x_1(n)$ and $x_2(n)$ we can define the product sequence as $x(n) = x_1(n)x_2^*(n)$. Then the corresponding complex convolution integral becomes

$$x(n) = x_1(n)x_2^*(n) \xleftrightarrow{z} X(z) = \frac{1}{2\pi j} \oint_{\mathcal{C}} X_1(v) X_2^*\left(\frac{z^*}{v^*}\right) v^{-1} dv \quad (3.2.21)$$

The proof of (3.2.21) is left as an exercise for the reader.

Parseval's relation. If $x_1(n)$ and $x_2(n)$ are complex-valued sequences, then

$$\sum_{n=-\infty}^{\infty} x_1(n)x_2^*(n) = \frac{1}{2\pi j} \oint_{\mathcal{C}} X_1(v) X_2^*\left(\frac{1}{v^*}\right) v^{-1} dv \quad (3.2.22)$$

provided that $r_{1l}r_{2l} < 1 < r_{1u}r_{2u}$, where $r_{1l} < |z| < r_{1u}$ and $r_{2l} < |z| < r_{2u}$ are the ROC of $X_1(z)$ and $X_2(z)$. The proof of (3.2.22) follows immediately by evaluating $X(z)$ in (3.2.21) at $z = 1$.

The Initial Value Theorem. If $x(n)$ is *causal* [i.e., $x(n) = 0$ for $n < 0$], then

$$x(0) = \lim_{z \rightarrow \infty} X(z) \quad (3.2.23)$$

Proof: Since $x(n)$ is causal, (3.1.1) gives

$$X(z) = \sum_{n=0}^{\infty} x(n)z^{-n} = x(0) + x(1)z^{-1} + x(2)z^{-2} + \dots$$

Obviously, as $z \rightarrow \infty$, $z^{-n} \rightarrow 0$ since $n > 0$ and (3.2.23) follows.

All the properties of the z-transform presented in this section are summarized in Table 3.2 for easy reference. They are listed in the same order as they have been introduced in the text. The conjugation properties and Parseval's relation are left as exercises for the reader.

We have now derived most of the z-transforms that are encountered in many practical applications. These z-transform pairs are summarized in Table 3.3 for easy reference. A simple inspection of this table shows that these z-transforms are all *rational functions* (i.e., ratios of polynomials in z^{-1}). As will soon become apparent, rational z-transforms are encountered not only as the z-transforms of various important signals but also in the characterization of discrete-time linear time-invariant systems described by constant-coefficient difference equations.

3.3 RATIONAL Z-TRANSFORMS

As indicated in Section 3.2, an important family of z-transforms are those for which $X(z)$ is a rational function, that is, a ratio of two polynomials in z^{-1} (or z). In this section we discuss some very important issues regarding the class of rational z-transforms.

3.3.1 Poles and Zeros

The *zeros* of a z-transform $X(z)$ are the values of z for which $X(z) = 0$. The *poles* of a z-transform are the values of z for which $X(z) = \infty$. If $X(z)$ is a rational function, then

$$X(z) = \frac{N(z)}{D(z)} = \frac{b_0 + b_1 z^{-1} + \dots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \dots + a_N z^{-N}} = \frac{\sum_{k=0}^M b_k z^{-k}}{\sum_{k=0}^N a_k z^{-k}} \quad (3.3.1)$$

If $a_0 \neq 0$ and $b_0 \neq 0$, we can avoid the negative powers of z by factoring out the terms $b_0 z^{-M}$ and $a_0 z^{-N}$ as follows:

$$X(z) = \frac{N(z)}{D(z)} = \frac{b_0 z^{-M} z^M + (b_1/b_0) z^{M-1} + \dots + b_M/b_0}{a_0 z^{-N} z^N + (a_1/a_0) z^{N-1} + \dots + a_N/a_0}$$

TABLE 32 PROPERTIES OF THE Z-TRANSFORM

Property	Time Domain	z-Domain	ROC
Notation	$x(n)$ $x_1(n)$ $x_2(n)$	$X(z)$ $X_1(z)$ $X_2(z)$	ROC: $r_2 < z < r_1$ ROC₁ ROC₂
Linearity	$a_1 x_1(n) + a_2 x_2(n)$	$a_1 X_1(z) + a_2 X_2(z)$	At least the intersection of ROC₁ and ROC₂
Time shifting	$x(n - k)$	$z^{-k} X(z)$	That of $X(z)$, except $z = 0$ if $k > 0$ and $z = \infty$ if $k < 0$
Scaling in the z-domain	$a^* x(n)$	$X(a^{-1} z)$	$ a r_2 < z < a r_1$
Time reversal	$x(-n)$	$X(z^{-1})$	$\frac{1}{r_1} < z < \frac{1}{r_2}$
Conjugation	$x^*(n)$	$X^*(z^*)$	ROC
Real part	$\text{Re}\{x(n)\}$	$\frac{1}{2}[X(z) + X^*(z^*)]$	Includes ROC
Imaginary part	$\text{Im}\{x(n)\}$	$\frac{1}{2j}[X(z) - X^*(z^*)]$	Includes ROC
Differentiation in the z-domain	$n x(n)$	$-z \frac{dX(z)}{dz}$	$r_2 < z < r_1$
Convolution	$x_1(n) * x_2(n)$	$X_1(z) X_2(z)$	At least, the intersection of ROC₁ and ROC₂
Correlation	$r_{x_1 x_2}(l) = x_1(l) * x_2(-l)$	$R_{x_1 x_2}(z) = X_1(z) X_2(z^{-1})$	At least, the intersection of ROC of $X_1(z)$ and $X_2(z^{-1})$
Initial value theorem	If $x(n)$ causal	$x(0) = \lim_{z \rightarrow \infty} X(z)$	
Multiplication	$x_1(n) x_2(n)$	$\frac{1}{2\pi j} \oint_C X_1(v) X_2\left(\frac{z}{v}\right) v^{-1} dv$	At least $r_{1l} r_{2l} < z < r_{1u} r_{2u}$
Parseval's relation	$\sum x_1(n) x_2^*(n)$	$= \frac{1}{2\pi j} \oint_C X_1(v) X_2^*(1/v^*) v^{-1} dv$	

TABLE 3.3 SOME COMMON Z-TRANSFORM PAIRS

	Signal, $x(n)$	z-Transform, $X(z)$	ROC
1	$\delta(n)$	1	All z
2	$u(n)$	$\frac{1}{1 - z^{-1}}$	$ z > 1$
3	$a^n u(n)$	$\frac{1}{1 - az^{-1}}$	$ z > a $
4	$na^n u(n)$	$\frac{az^{-1}}{(1 - az^{-1})^2}$	$ z > a $
5	$-a^n u(-n - 1)$	$\frac{1}{1 - az^{-1}}$	$ z < a $
6	$-na^n u(-n - 1)$	$\frac{az^{-1}}{(1 - az^{-1})^2}$	$ z < a $
7	$(\cos \omega_0 n) u(n)$	$\frac{1 - z^{-1} \cos \omega_0}{1 - 2z^{-1} \cos \omega_0 + z^{-2}}$	$ z > 1$
8	$(\sin \omega_0 n) u(n)$	$\frac{z^{-1} \sin \omega_0}{1 - 2z^{-1} \cos \omega_0 + z^{-2}}$	$ z > 1$
9	$(a^n \cos \omega_0 n) u(n)$	$\frac{1 - az^{-1} \cos \omega_0}{1 - 2az^{-1} \cos \omega_0 + a^2 z^{-2}}$	$ z > a $
10	$(a^n \sin \omega_0 n) u(n)$	$\frac{az^{-1} \sin \omega_0}{1 - 2az^{-1} \cos \omega_0 + a^2 z^{-2}}$	$ z > a $

Since $N(z)$ and $D(z)$ are polynomials in z , they can be expressed in factored form as

$$X(z) = \frac{N(z)}{D(z)} = \frac{b_0}{a_0} z^{-M+N} \frac{(z - z_1)(z - z_2) \cdots (z - z_M)}{(z - p_1)(z - p_2) \cdots (z - p_N)}$$

$$X(z) = G z^{N-M} \frac{\prod_{k=1}^M (z - z_k)}{\prod_{k=1}^N (z - p_k)} \quad (3.3.2)$$

where $G \equiv b_0/a_0$. Thus $X(z)$ has M finite zeros at $z = z_1, z_2, \dots, z_M$ (the roots of the numerator polynomial), N finite poles at $z = p_1, p_2, \dots, p_N$ (the roots of the denominator polynomial), and $|N - M|$ zeros (if $N > M$) or poles (if $N < M$) at the origin $z = 0$. Poles or zeros may also occur at $z = \infty$. A zero exists at $z = \infty$ if $X(\infty) = 0$ and a pole exists at $z = \infty$ if $X(\infty) = \infty$. If we count the poles and zeros at zero and infinity, we find that $X(z)$ has exactly the same number of poles as zeros.

We can represent $X(z)$ graphically by a **pole-zero plot** (or **pattern**) in the complex plane, which shows the location of poles by crosses (x) and the location of zeros by circles (o). The multiplicity of multiple-order poles or zeros is indicated by a number close to the corresponding cross or circle. Obviously, by definition, the ROC of a **z-transform** should not contain any poles.

Example 33.1

Determine the pole-zero plot for the signal

$$x(n) = a^n u(n) \quad a > 0$$

Solution From Table 3.3 we find that

$$X(z) = \frac{1}{1 - az^{-1}} = \frac{z}{z - a} \quad \text{ROC: } |z| > a$$

Thus $X(z)$ has one zero at $z_1 = 0$ and one pole at $p_1 = a$. The pole-zero plot is shown in Fig. 3.7. Note that the pole $p_1 = a$ is not included in the ROC since the z -transform does not converge at a pole.

Figure 3.7 Pole-zero plot for the causal exponential signal $x(n) = a^n u(n)$

Example 3.3.2

Determine the pole-zero plot for the signal

$$x(n) = \begin{cases} a^n, & 0 \leq n \leq M-1 \\ 0, & \text{elsewhere} \end{cases}$$

where $a > 0$.

Solution From the definition (3.1.1) we obtain

$$X(z) = \sum_{n=0}^{M-1} (az^{-1})^n = \frac{1 - (az^{-1})^M}{1 - az^{-1}} = \frac{z^M - a^M}{z^{M-1}(z - a)}$$

Since $a > 0$, the equation $z^M = a^M$ has M roots at

$$z_k = ae^{j2\pi k/M} \quad k = 0, 1, \dots, M-1$$

The zero $z_0 = a$ cancels the pole at $z = a$. Thus

$$X(z) = \frac{(z - z_1)(z - z_2) \cdots (z - z_{M-1})}{z^{M-1}}$$

which has $M-1$ zeros and $M-1$ poles, located as shown in Fig. 3.8 for $M=8$. Note that the ROC is the entire z -plane except $z=0$ because of the $M-1$ poles located at the origin.

Figure 3.8 Pole-zero pattern for the finite-duration signal $x(n) = a^n$, $0 \leq n \leq M-1$ ($a > 0$), for $M = 8$.

Clearly, if we are given a pole-zero plot, we can determine $X(z)$, by using (3.3.2), to within a scaling factor G . This is illustrated in the following example.

Example 3.3.3

Determine the z -transform and the signal that corresponds to the pole-zero plot of Fig. 3.9.

Solution There are two zeros ($M = 2$) at $z_1 = r \cos \omega_0$ and $z_2 = r \cos \omega_0$ and two poles ($N = 2$) at $p_1 = r e^{j\omega_0}$, $p_2 = r e^{-j\omega_0}$. By substitution of these relations into (3.3.2), we obtain

$$X(z) = G \frac{(z - z_1)(z - z_2)}{(z - p_1)(z - p_2)} = G \frac{z(z - r \cos \omega_0)}{(z - r e^{j\omega_0})(z - r e^{-j\omega_0})} \quad \text{ROC: } |z| > r$$

After some simple algebraic manipulations, we obtain

$$X(z) = G \frac{1 - r z^{-1} \cos \omega_0}{1 - 2r z^{-1} \cos \omega_0 + r^2 z^{-2}} \quad \text{ROC: } |z| > r$$

From Table 3.3 we find that

$$x(n) = G(r^n \cos \omega_0 n) u(n)$$

From Example 3.3.3, we see that the product $(z - p_1)(z - p_2)$ results in a polynomial with real coefficients, when p_1 and p_2 are complex conjugates. In

Figure 3.9 Pole-zero pattern for Example 3.3.3.

general, if a polynomial has real coefficients, its roots are either real or occur in complex-conjugate pairs.

As we have seen, the z -transform $X(z)$ is a complex function of the complex variable $z = \text{Re}(z) + j\text{Im}(z)$. Obviously, $|X(z)|$, the magnitude of $X(z)$, is a real and positive function of z . Since z represents a point in the complex plane, $|X(z)|$ is a two-dimensional function and describes a "surface." This is illustrated in Fig. 3.10(a) for the z -transform

$$X(z) = \frac{z^{-1} - z^{-2}}{1 + 1.2732z^{-1} + 0.81z^{-2}} \quad (3.3.3)$$

Figure 3.10 Graph of $|X(z)|$ for the z -transform in (3.3.3). [Reproduced with permission from *Introduction to Systems Analysis*, by T. H. Glisson, © 1985 by McGraw-Hill Book Company.]

which has one zero at $z_1 = 1$ and two poles at $p_1, p_2 = 0.9e^{\pm j\pi/4}$. Note the high peaks near the singularities (poles) and the deep valley close to the zero. Figure 3.10(b) illustrates the graph of $|X(z)|$ for $z = e^{j\omega}$.

3.3.2 Pole Location and Time-Domain Behavior for Causal Signals

In this subsection we consider the relation between the z-plane location of a pole pair and the form (shape) of the corresponding signal in the time domain. The discussion is based generally on the **collection** of z-transform pairs given in Table 3.3 and the results in the preceding subsection. We deal exclusively with real, causal signals. In particular, we see that the characteristic behavior of causal signals depends on whether the poles of the transform are contained in the region $|z| < 1$, or in the region $|z| > 1$, or on the circle $|z| = 1$. Since the circle $|z| = 1$ has a radius of 1, it is called the *unit circle*.

If a real signal has a z-transform with one pole, this pole has to be real. The only such signal is the real exponential

$$x(n) = a^n u(n) \longleftrightarrow X(z) = \frac{1}{1 - az^{-1}} \quad \text{ROC: } |z| > |a|$$

having one zero at $z_1 = 0$ and one pole at $p_1 = a$ on the real axis. Figure 3.11

Figure 3.11 Time-domain behavior of a single-real pole causal signal as a function of the location of the pole with respect to the unit circle.

illustrates the behavior of the signal with respect to the location of the pole relative to the unit circle. The signal is decaying if the pole is inside the unit circle, fixed if the pole is on the unit circle, and growing if the pole is outside the unit circle. In addition, a negative pole results in a signal that alternates in sign. Obviously, causal signals with poles outside the unit circle become unbounded, cause overflow in digital systems, and in general, should be avoided.

A causal real signal with a double real pole has the form

$$x(n) = na^n u(n)$$

(see Table 3.3) and its behavior is illustrated in Fig. 3.12. Note that in contrast to the single-pole signal, a double real pole on the unit circle results in an unbounded signal.

Figure 3.13 illustrates the case of a pair of complex-conjugate poles. According to Table 3.3, this configuration of poles results in an exponentially weighted sinusoidal signal. The distance r of the poles from the origin determines the envelope of the sinusoidal signal and their angle with the real positive axis, its relative frequency. Note that the amplitude of the signal is growing if $r > 1$, constant if $r = 1$ (sinusoidal signals), and decaying if $r < 1$.

Figure 3.13 Time-domain behavior of causal signals corresponding to a double ($m = 2$) real pole, as a function of the pole location.

Figure 3.13 A pair of complex-conjugate poles corresponds to causal signals with oscillatory behavior.

Finally, Fig. 3.14 shows the behavior of a causal signal with a double pair of poles on the unit circle. This reinforces the corresponding results in Fig. 3.12 and illustrates that multiple poles on the unit circle should be treated with great **care**.

To summarize, causal real signals with simple real **poles** or simple complex-conjugate pairs of poles, which are inside or on the unit circle are always bounded in amplitude. Furthermore, a signal with a pole (or a complex-conjugate **pair** of poles) near the origin decays more rapidly than one associated with a pole near (but inside) the unit circle. **Thus** the time behavior of a signal depends strongly **on** the location of its poles relative to the unit circle. Zeros also affect the behavior of a signal but not as strongly as poles. For example, in the

Figure 3.13 Causal signal corresponding to a double pair of complex-conjugate poles on the unit circle.

case of sinusoidal signals, the presence and location of zeros affects only their phase.

At this point, it should be stressed that everything we have said about causal signals applies as well to causal LTI systems, since their impulse response is a causal signal. Hence if a pole of a system is outside the unit circle, the impulse response of the system becomes unbounded and, consequently, the system is unstable.

3.3.3 The System Function of a Linear Time-Invariant System

In Chapter 2 we demonstrated that the output of a (relaxed) linear time-invariant system to an input sequence $x(n)$ can be obtained by computing the convolution of $x(n)$ with the unit sample response of the system. The convolution property, derived in Section 3.2, allows us to express this relationship in the z -domain as

$$Y(z) = H(z)X(z) \quad (3.3.4)$$

where $Y(z)$ is the z -transform of the output sequence $y(n)$, $X(z)$ is the z -transform of the input sequence $x(n)$ and $H(z)$ is the z -transform of the unit sample response $h(n)$.

If we know $h(n)$ and $x(n)$, we can determine their corresponding z -transforms $H(z)$ and $X(z)$, multiply them to obtain $Y(z)$, and therefore determine $y(n)$ by evaluating the inverse z -transform of $Y(z)$. Alternatively, if we know $x(n)$ and we observe the output $y(n)$ of the system, we can determine the unit sample response by first solving for $H(z)$ from the relation

$$H(z) = \frac{Y(z)}{X(z)} \quad (3.3.5)$$

and then evaluating the inverse z -transform of $H(z)$.

Since

$$H(z) = \sum_{n=-\infty}^{\infty} h(n)z^{-n} \quad (3.3.6)$$

it is clear that $H(z)$ represents the z-domain characterization of a system, whereas $h(n)$ is the corresponding time-domain characterization of the system. In other words, $H(z)$ and $h(n)$ are equivalent descriptions of a system in the two domains. The transform $H(z)$ is called the *system function*,

The relation in (3.3.5) is particularly useful in obtaining $H(z)$ when the system is described by a linear constant-coefficient difference equation of the form

$$y(n) = - \sum_{k=1}^N a_k y(n-k) + \sum_{k=0}^M b_k x(n-k) \quad (3.3.7)$$

In this case the system function can be determined directly from (3.3.7) by computing the z-transform of both sides of (3.3.7). Thus, by applying the time-shifting property, we obtain

$$\begin{aligned} Y(z) &= - \sum_{k=1}^N a_k Y(z) z^{-k} + \sum_{k=0}^M b_k X(z) z^{-k} \\ Y(z) \left(1 + \sum_{k=1}^N a_k z^{-k} \right) &= X(z) \left(\sum_{k=0}^M b_k z^{-k} \right) \\ \frac{Y(z)}{X(z)} &= \frac{\sum_{k=0}^M b_k z^{-k}}{1 + \sum_{k=1}^N a_k z^{-k}} \end{aligned}$$

or, equivalently,

$$H(z) = \frac{\sum_{k=0}^M b_k z^{-k}}{1 + \sum_{k=1}^N a_k z^{-k}} \quad (3.3.8)$$

Therefore, a linear time-invariant system described by a constant-coefficient difference equation has a rational system function.

This is the general form for the system function of a system described by a linear constant-coefficient difference equation. From this general form we obtain two important special forms. First, if $a_k = 0$ for $1 \leq k \leq N$, (3.3.8) reduces to

$$\begin{aligned} H(z) &= \sum_{k=0}^M b_k z^{-k} \\ &= \frac{1}{z^M} \sum_{k=0}^M b_k z^{M-k} \end{aligned} \quad (3.3.9)$$

In this case, $H(z)$ contains M zeros, whose values are determined by the system parameters $\{b_k\}$, and an M th-order pole at the origin $z = 0$. Since the system contains only trivial poles (at $z = 0$) and M nontrivial zeros, it is called

an all-zero system. Clearly, such a system has a finite-duration impulse response (FIR), and it is called an FIR system or a moving average (MA) system.

On the other hand, if $b_k = 0$ for $1 \leq k \leq M$, the system function reduces to

$$\begin{aligned} H(z) &= \frac{b_0}{1 + \sum_{k=1}^N a_k z^{-k}} \\ &= \frac{b_0 z^N}{\sum_{k=0}^N a_k z^{N-k}} \quad a_0 \equiv 1 \end{aligned} \quad (3.3.10)$$

In this case $H(z)$ consists of N poles, whose values are determined by the system parameters $\{a_k\}$ and an N th-order zero at the origin $z = 0$. We usually do not make reference to these trivial zeros. Consequently, the system function in (3.3.10) contains only nontrivial poles and the corresponding system is called an *all-pole system*. Due to the presence of poles, the impulse response of such a system is infinite in duration, and hence it is an IIR system.

The general form of the system function given by (3.3.8) contains both poles and zeros, and hence the corresponding system is called a *pole-zero system*, with N poles and M zeros. Poles and/or zeros at $z = 0$ and $z = \infty$ are implied but are not counted explicitly. Due to the presence of poles, a pole-zero system is an IIR system.

The following example illustrates the procedure for determining the system function and the unit sample response from the difference equation.

Example 3.3.4

Determine the system function and the unit sample response of the system described by the difference equation

$$y(n) = \frac{1}{2}y(n-1) + 2x(n)$$

Solution By computing the z -transform of the difference equation, we obtain

$$Y(z) = \frac{1}{2}z^{-1}Y(z) + 2X(z)$$

Hence the system function is

$$\frac{Y(z)}{X(z)} \equiv H(z) = \frac{2}{1 - \frac{1}{2}z^{-1}}$$

This system has a pole at $z = \frac{1}{2}$ and a zero at the origin. Using Table 3.3 we obtain the inverse transform

$$h(n) = 2\left(\frac{1}{2}\right)^n u(n)$$

This is the unit sample response of the system.

We have now demonstrated that rational **z-transforms** are encountered in **commonly** used systems and in the characterization of linear time-invariant systems. In Section 3.4 we describe several methods for **determining** the inverse z-transform of rational functions.

3.4 INVERSION OF THE Z-TRANSFORM

As we saw in Section 3.1.2, the inverse z-transform is **formally** given by

$$x(n) = \frac{1}{2\pi j} \oint_C X(z) z^{n-1} dz \quad (3.4.1)$$

where the integral is a contour integral over a closed path C that encloses the origin and lies within the region of convergence of $X(z)$. For simplicity, C can be taken as a circle in the ROC of $X(z)$ in the z -plane.

There are three methods that are often used for the evaluation of the inverse **z-transform** in practice:

1. Direct evaluation of (3.4.1), by contour integration.
2. Expansion into a series of terms, in the variables z , and z^{-1} .
3. Partial-fraction expansion and table lookup.

3.4.1 The Inverse z-Transform by Contour Integration

In this section we demonstrate the use of the Cauchy residue theorem to determine the inverse z-transform directly from the contour integral.

Cauchy residue theorem. Let $f(z)$ be a function of the complex variable z and C be a closed path in the z -plane. If the derivative $df(z)/dz$ exists on and inside the contour C and if $f(z)$ has no poles at $z = z_0$, then

$$\frac{1}{2\pi j} \oint_C \frac{f(z)}{z - z_0} dz = \begin{cases} f(z_0), & \text{if } z_0 \text{ is inside } C \\ 0, & \text{if } z_0 \text{ is outside } C \end{cases} \quad (3.4.2)$$

More generally, if the $(k+1)$ -order derivative of $f(z)$ exists and $f(z)$ has no poles at $z = z_0$, then

$$\frac{1}{2\pi j} \oint_C \frac{f(z)}{(z - z_0)^{k+1}} dz = \begin{cases} \frac{1}{(k+1)!} \frac{d^{k+1} f(z)}{dz^{k+1}} \Big|_{z=z_0}, & \text{if } z_0 \text{ is inside } C \\ 0, & \text{if } z_0 \text{ is outside } C \end{cases} \quad (3.4.3)$$

The values on the right-hand side of (3.4.2) and (3.4.3) are called the residues of the pole at $z = z_0$. The results in (3.4.2) and (3.4.3) are two forms of the Cauchy residue theorem.

We can apply (3.4.2) and (3.4.3) to obtain the values of more general **contour** integrals. To be specific, suppose that the integrand of the contour integral is

$P(z) = f(z)/g(z)$, where $f(z)$ has no poles inside the contour C and $g(z)$ is a polynomial with distinct (simple) roots $z_1, z_2, \dots, z_n$ inside C . Then

$$\begin{aligned}\frac{1}{2\pi j} \oint_C \frac{f(z)}{g(z)} dz &= \frac{1}{2\pi j} \oint_C \left[\sum_{i=1}^n \frac{A_i(z)}{z - z_i} \right] dz \\ &= \sum_{i=1}^n \frac{1}{2\pi j} \oint_C \frac{A_i(z)}{z - z_i} dz \\ &= \sum_{i=1}^n A_i(z_i)\end{aligned}\quad (3.4.4)$$

where

$$A_i(z) = (z - z_i)P(z) = (z - z_i) \frac{f(z)}{g(z)} \quad (3.4.5)$$

The values $\{A_i(z_i)\}$ are residues of the corresponding poles at $z = z_i, i = 1, 2, \dots, n$. Hence the value of the contour integral is equal to the sum of the residues of all the poles inside the contour C .

We observe that (3.4.4) was obtained by performing a partial-fraction expansion of the integrand and applying (3.4.2). When $g(z)$ has multiple-order roots as well as simple roots inside the contour, the partial-fraction expansion, with appropriate modifications, and (3.4.3) can be used to evaluate the residues at the corresponding poles.

In the case of the inverse z-transform, we have

$$\begin{aligned}x(n) &= \frac{1}{2\pi j} \oint_C X(z) z^{n-1} dz \\ &= \sum_{\text{all poles } \{z_i\} \text{ inside } C} [\text{residue of } X(z) z^{n-1} \text{ at } z = z_i] \\ &= \sum_i (z - z_i) X(z) z^{n-1} \big|_{z=z_i}\end{aligned}\quad (3.4.6)$$

provided that the poles $\{z_i\}$ are simple. If $X(z)z^{n-1}$ has no poles inside the contour C for one or more values of n , then $x(n) = 0$ for these values.

The following example illustrates the evaluation of the inverse z-transform by use of the Cauchy residue theorem.

Example 3.4.1

Evaluate the inverse z-transform of

$$X(z) = \frac{1}{1 - az^{-1}} \quad |z| > |a|$$

using the complex inversion integral.

Solution We have

$$x(n) = \frac{1}{2\pi j} \oint_C \frac{z^{n-1}}{1 - az^{-1}} dz = \frac{1}{2\pi j} \oint_C \frac{z^n dz}{z - a}$$

where C is a circle at radius greater than $|a|$. We shall evaluate this integral using (3.4.2) with $f(z) = z^n$. We distinguish two cases.

1. If $n \geq 0$, $f(z)$ has only zeros and hence no poles inside C . The only pole inside C is $z = a$. Hence

$$x(n) = f(z_0) = a^n \quad n \geq 0$$

2. If $n < 0$, $f(z) = z^n$ has an n th-order pole at $z = 0$, which is also inside C . Thus there are contributions from both poles. For $n = -1$ we have

$$x(-1) = \frac{1}{2\pi j} \oint_C \frac{1}{z(z-a)} dz = \frac{1}{z-a} \Big|_{z=0} + \frac{1}{z} \Big|_{z=a} = 0$$

If $n = -2$, we have

$$x(-2) = \frac{1}{2\pi j} \oint_C \frac{z^2}{z^2(z-a)} dz = \frac{d}{dz} \left(\frac{1}{z-a} \right) \Big|_{z=0} + \frac{1}{z^2} \Big|_{z=a} = 0$$

By continuing in the same way we can show that $x(n) = 0$ for $n < 0$. Thus

$$x(n) = a^n u(n)$$

3.4.2 The Inverse z-Transform by Power Series Expansion

The basic idea in this method is the following: Given a z-transform $X(z)$ with its corresponding ROC, we can expand $X(z)$ into a power series of the form

$$X(z) = \sum_{n=-\infty}^{\infty} c_n z^{-n} \quad (3.4.7)$$

which converges in the given ROC. Then, by the uniqueness of the z-transform, $x(n) = c_n$ for all n . When $X(z)$ is rational, the expansion can be performed by long division.

To illustrate this technique, we will invert some z-transforms involving the same expression for $X(z)$, but different ROC. This will also serve to emphasize again the importance of the ROC in dealing with z-transforms.

Example 3.4.2

Determine the inverse z-transform of

$$X(z) = \frac{1}{1 - 1.5z^{-1} + 0.5z^{-2}}$$

when

- (a) ROC: $|z| > 1$
 (b) ROC: $|z| < 0.5$

Solution

- (a) Since the ROC is the exterior of a circle, we expect $x(n)$ to be a causal signal. Thus we seek a power series expansion in negative powers of z . By dividing

the numerator of $X(z)$ by its denominator, we obtain the power series

$$X(z) = \frac{1}{1 - \frac{3}{2}z^{-1} + \frac{1}{2}z^{-2}} = 1 + \frac{3}{2}z^{-1} + \frac{7}{4}z^{-2} + \frac{15}{8}z^{-3} + \frac{31}{16}z^{-4} + \dots$$

By comparing this relation with (3.1.1), we conclude that

$$x(n) = \{1, \frac{3}{2}, \frac{7}{4}, \frac{15}{8}, \frac{31}{16}, \dots\}$$

Note that in each step of the long-division process, we eliminate the lowest-power term of $\frac{1}{1 - \frac{3}{2}z^{-1} + \frac{1}{2}z^{-2}}$.

- (b) In this case the ROC is the interior of a circle. Consequently, the signal $x(n]$ is anticausal. To obtain a power series expansion in positive powers of z , we perform the long division in the following way:

$$\begin{array}{r} \frac{2z^2 + 6z^3 + 14z^4 + 30z^5 + 62z^6 + \dots}{\frac{1}{2}z^{-2} - \frac{3}{2}z^{-1} + 1)1} \\ \underline{1 - 3z + 2z^2} \\ 3z - 9z^2 + 6z^3 \\ \underline{7z^2 - 6z^3} \\ 7z^2 - 21z^3 + 14z^4 \\ \underline{15z^3 - 14z^4} \\ 15z^3 - 45z^4 + 30z^5 \\ \underline{31z^4 - 30z^5} \end{array}$$

Thus

$$X(z) = \frac{1}{1 - \frac{3}{2}z^{-1} + \frac{1}{2}z^{-2}} = 2z^2 + 6z^3 + 14z^4 + 30z^5 + 62z^6 + \dots$$

In this case $x(n) = 0$ for $n \geq 0$. By comparing this result to (3.1.1), we conclude that

$$x(n) = \{\dots, 62, 30, 14, 6, 2, 0, 0\}$$

We observe that in each step of the long-division process, the lowest-power term of z is eliminated. We emphasize that in the case of anticausal signals we simply carry out the Long division by writing down the two polynomials in "reverse" order (i.e., starting with the most negative term on the left).

From this example we note that, in general, the method of long division will not provide answers for $x(n)$ when n is large because the long division becomes tedious. Although, the method provides a direct evaluation of $x(n)$, a closed-form solution is not possible, except if the resulting pattern is simple enough to infer the general term $x(n)$. Hence this method is used only if one wished to determine the values of the **first** few samples of the signal.

Example 343

Determine the inverse z-transform of

$$X(z) = \log(1 + az^{-1}) \quad |z| > |a|$$

Solution Using the power series expansion for $\log(1+x)$, with $|x| < 1$, we have

$$X(z) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1} a^n z^{-n}}{n}$$

Thus

$$x(n) = \begin{cases} (-1)^{n+1} \frac{a^n}{n}, & n \geq 1 \\ 0, & n \leq 0 \end{cases}$$

Expansion of irrational functions into power series can be obtained from tables.

3.4.3 The Inverse z-Transform by Partial-Fraction Expansion

In the table lookup method, we attempt to express the function $X(z)$ as a linear combination

$$X(z) = \alpha_1 X_1(z) + \alpha_2 X_2(z) + \dots + \alpha_K X_K(z) \quad (3.4.8)$$

where $X_1(z), \dots, X_K(z)$ are expressions with inverse transforms $x_1(n), \dots, x_K(n)$ available in a table of z-transform pairs. If such a decomposition is possible, then $x(n)$, the inverse z-transform of $X(z)$, can easily be found using the linearity property as

$$x(n) = \alpha_1 x_1(n) + \alpha_2 x_2(n) + \dots + \alpha_K x_K(n) \quad (3.4.9)$$

This approach is particularly useful if $X(z)$ is a rational function, as in (3.3.1). Without loss of generality, we assume that $a_0 = 1$, so that (3.3.1) can be expressed as

$$X(z) = \frac{N(z)}{D(z)} = \frac{b_0 + b_1 z^{-1} + \dots + b_M z^{-M}}{1 + a_1 z^{-1} + \dots + a_N z^{-N}} \quad (3.4.10)$$

Note that if $a_0 \neq 1$, we can obtain (3.4.10) from (3.3.1) by dividing both numerator and denominator by a_0 .

A rational function of the form (3.4.10) is called proper if $a_N \neq 0$ and $M < N$. From (3.3.2) it follows that this is equivalent to saying that the number of finite zeros is less than the number of finite poles.

An improper rational function ($M \geq N$) can always be written as the sum of a polynomial and a proper rational function. This procedure is illustrated by the following example.

Example 344

Express the improper rational transform

$$X(z) = \frac{1 + 3z^{-1} + \frac{11}{6}z^{-2} + \frac{1}{3}z^{-3}}{1 + \frac{5}{6}z^{-1} + \frac{1}{6}z^{-2}}$$

in terms of a polynomial and a proper function.

Solution First, we note that we should reduce the numerator so that the terms z^{-2} and z^{-3} are eliminated. Thus we should carry out the long division with these two polynomials written in reverse order. We stop the division when the order of the remainder becomes z^{-1} . Then we obtain

$$X(z) = 1 + 2z^{-1} + \frac{\frac{1}{6}z^{-1}}{1 + \frac{5}{6}z^{-1} + \frac{1}{6}z^{-2}}$$

In general, any improper rational function ($M \geq N$) can be expressed as

$$X(z) = \frac{N(z)}{D(z)} = c_0 + c_1 z^{-1} + \cdots + c_{M-N} z^{-(M-N)} + \frac{N_1(z)}{D(z)} \quad (3.4.11)$$

The inverse z -transform of the polynomial can easily be found by inspection. We focus our attention on the inversion of proper rational transforms, since any improper function can be transformed into a proper function by using (3.4.11). We carry out the development in two steps. First, we perform a partial fraction expansion of the proper rational function and then we invert each of the terms.

Let $X(z)$ be a proper rational function, that is,

$$X(z) = \frac{N(z)}{D(z)} = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{1 + a_1 z^{-1} + \cdots + a_N z^{-N}} \quad (3.4.12)$$

where

$$a_N \neq 0 \quad \text{and} \quad M < N$$

To simplify our discussion we eliminate negative powers of z by multiplying both the numerator and denominator of (3.4.12) by z^N . This results in

$$X(z) = \frac{b_0 z^N + b_1 z^{N-1} + \cdots + b_M z^{N-M}}{z^N + a_1 z^{N-1} + \cdots + a_N} \quad (3.4.13)$$

which contains only positive powers of z . Since $N > M$, the function

$$\frac{X(z)}{z} = \frac{b_0 z^{N-1} + b_1 z^{N-2} + \cdots + b_M z^{N-M-1}}{z^N + a_1 z^{N-1} + \cdots + a_N} \quad (3.4.14)$$

is also always proper.

Our task in performing a partial-fraction expansion is to express (3.4.14) or, equivalently, (3.4.12) as a sum of simple fractions. For this purpose we first factor the denominator polynomial in (3.4.14) into factors that contain the poles $p_1, p_2, \dots, p_N$ of $X(z)$. We distinguish two cases.

Distinct poles. Suppose that the poles $p_1, p_2, \dots, p_N$ are all different (distinct). Then we seek an expansion of the form

$$\frac{X(z)}{z} = \frac{A_1}{z - p_1} + \frac{A_2}{z - p_2} + \cdots + \frac{A_N}{z - p_N} \quad (3.4.15)$$

The problem is to determine the coefficients $A_1, A_2, \dots, A_N$. There are two ways to solve this problem, as illustrated in the following example.

Example 3.45

Determine the partial-fraction expansion of the proper function

$$X(z) = \frac{1}{1 - 1.5z^{-1} + 0.5z^{-2}} \quad (3.4.16)$$

Solution First we eliminate the negative powers, by multiplying both numerator and denominator by z^2 . Thus

$$X(z) = \frac{z^2}{z^2 - 1.5z + 0.5}$$

The poles of $X(z)$ are $p_1 = 1$ and $p_2 = 0.5$. Consequently, the expansion of the form (3.4.15) is

$$\frac{X(z)}{z} = \frac{z}{(z-1)(z-0.5)} = \frac{A_1}{z-1} + \frac{A_2}{z-0.5} \quad (3.4.17)$$

A very simple method to determine A_1 and A_2 is to multiply the equation by the denominator term $(z-1)(z-0.5)$. Thus we obtain

$$z = (z-0.5)A_1 + (z-1)A_2 \quad (3.4.18)$$

Now if we set $z = p_1 = 1$ in (3.4.18), we eliminate the term involving A_2 . Hence

$$1 = (1-0.5)A_1$$

Thus we obtain the result $A_1 = 2$. Next we return to (3.4.18) and set $z = p_2 = 0.5$, thus eliminating the term involving A_1 , so we have

$$0.5 = (0.5-1)A_2$$

and hence $A_2 = -1$. Therefore, the result of the partial-fraction expansion is

$$\frac{X(z)}{z} = \frac{2}{z-1} - \frac{1}{z-0.5} \quad (3.4.19)$$

The example given above suggests that we can determine the coefficients $A_1, A_2, \dots, A_N$, by multiplying both sides of (3.4.15) by each of the terms $(z - p_k)$, $k = 1, 2, \dots, N$, and evaluating the resulting expressions at the corresponding pole positions, $p_1, p_2, \dots, p_N$. Thus we have, in general,

$$\frac{(z - p_k)X(z)}{z} = \frac{(z - p_k)A_1}{z - p_1} + \dots + A_k + \dots + \frac{(z - p_k)A_N}{z - p_N} \quad (3.4.20)$$

Consequently, with $z = p_k$, (3.4.20) yields the k th coefficient as

$$A_k = \left. \frac{(z - p_k)X(z)}{z} \right|_{z=p_k} \quad k = 1, 2, \dots, N \quad (3.4.21)$$

Example 3.46

Determine the partial-fraction expansion of

$$X(z) = \frac{1 + z^{-1}}{1 - z^{-1} + 0.5z^{-2}} \quad (3.4.22)$$

Solution To eliminate negative powers of: in (3.4.22), we multiply both numerator and denominator by z^2 . **Thus**

$$\frac{X(z)}{z} = \frac{z+1}{z^2 - z + 0.5}$$

The poles of $X(z)$ are complex conjugates

$$p_1 = \frac{1}{2} + j\frac{1}{2}$$

and

$$p_2 = \frac{1}{2} - j\frac{1}{2}$$

Since $p_1 \neq p_2$, we seek an expansion of the form (3.4.15). Thus

$$\frac{X(z)}{z} = \frac{z+1}{(z-p_1)(z-p_2)} = \frac{A_1}{z-p_1} + \frac{A_2}{z-p_2}$$

To obtain A_1 and A_2 , we use the formula (3.4.21). Thus we obtain

$$A_1 = \left. \frac{(z-p_1)X(z)}{z} \right|_{z=p_1} = \left. \frac{z+1}{z-p_2} \right|_{z=p_1} = \frac{\frac{1}{2} + j\frac{1}{2} + 1}{\frac{1}{2} + j\frac{1}{2} - \frac{1}{2} - j\frac{1}{2}} = \frac{1}{2} - j\frac{3}{2}$$

$$A_2 = \left. \frac{(z-p_2)X(z)}{z} \right|_{z=p_2} = \left. \frac{z+1}{z-p_1} \right|_{z=p_2} = \frac{\frac{1}{2} - j\frac{1}{2} + 1}{\frac{1}{2} - j\frac{1}{2} - \frac{1}{2} + j\frac{1}{2}} = \frac{1}{2} + j\frac{3}{2}$$

The expansion (3.4.15) and the formula (3.4.21) hold for both real and complex poles. The only constraint is that all poles be distinct. We also note that $A_2 = A_1^*$. It can be easily seen that this is a consequence of the fact that $p_2 = p_1^*$. In other words, **complex-conjugate poles result in complex-conjugate coefficients in the partial-fraction expansion**. This simple result will prove very useful later in our discussion.

Multiple-order poles. If $X(z)$ has a pole of multiplicity l , that is, it contains in its denominator the factor $(z-p_k)^l$, then the expansion (3.4.15) is no longer true. In this case a different expansion is needed. First, we investigate the case of a double pole (i.e., $l=2$).

Example 3.4.7

Determine the partial-fraction expansion of

$$X(z) = \frac{z^2}{(1+z^{-1})(1-z^{-1})^2} \quad (3.4.23)$$

Solution First, we express (3.4.23) in terms of positive powers of z , in the form

$$\frac{X(z)}{z} = \frac{z^2}{(z+1)(z-1)^2}$$

$X(z)$ has a simple pole at $p_1 = -1$ and a double pole $p_2 = p_3 = 1$. In such a case the appropriate partial-fraction expansion is

$$\frac{X(z)}{z} = \frac{z^2}{(z+1)(z-1)^2} = \frac{A_1}{z+1} + \frac{A_2}{z-1} + \frac{A_3}{(z-1)^2} \quad (3.4.24)$$

The problem is to determine the coefficients A_1 , A_2 , and A_3 .

We proceed as in the case of distinct poles. To determine A_1 , we multiply both sides of (3.4.24) by $(z+1)$ and evaluate the result at $z = -1$. Thus (3.4.24) becomes

$$\frac{(z+1)X(z)}{z} = A_1 + \frac{z+1}{z-1}A_2 + \frac{z+1}{(z-1)^2}A_3$$

which, when evaluated at $z = -1$, yields

$$A_1 = \left. \frac{(z+1)X(z)}{z} \right|_{z=-1} = \frac{1}{4}$$

Next, if we multiply both sides of (3.4.24) by $(z-1)^2$, we obtain

$$\frac{(z-1)^2 X(z)}{z} = \frac{(z-1)^2}{z+1} A_1 + (z-1) A_2 + A_3 \quad (3.4.25)$$

Now, if we evaluate (3.4.25) at $z = 1$, we obtain A_3 . Thus

$$A_3 = \left. \frac{(z-1)^2 X(z)}{z} \right|_{z=1} = \frac{1}{2}$$

The remaining coefficient A_2 can be obtained by differentiating both sides of (3.4.25) with respect to z and evaluating the result at $z = 1$. Note that it is not necessary formally to carry out the differentiation of the right-hand side of (3.4.25), since all terms except A_2 vanish when we set $z = 1$. Thus

$$A_2 = \frac{d}{dz} \left[\frac{(z-1)^2 X(z)}{z} \right]_{z=1} = \frac{3}{4} \quad (3.4.26)$$

The generalization of the procedure in the example above to the case of an l th-order pole $(z - p_k)^l$ is straightforward. The partial-fraction expansion must contain the terms

$$\frac{A_{1k}}{z - p_k} + \frac{A_{2k}}{(z - p_k)^2} + \cdots + \frac{A_{lk}}{(z - p_k)^l}$$

The coefficients $\{A_{ik}\}$ can be evaluated through differentiation as illustrated in Example 3.4.7 for $l = 2$.

Now that we have performed the partial-fraction expansion, we are ready to take the final step in the inversion of $X(z)$. First, let us consider the case in which $X(z)$ contains distinct poles. From the partial-fraction expansion (3.4.15), it easily follows that

$$X(z) = A_1 \frac{1}{1 - p_1 z^{-1}} + A_2 \frac{1}{1 - p_2 z^{-1}} + \cdots + A_N \frac{1}{1 - p_N z^{-1}} \quad (3.4.27)$$

The inverse z -transform, $x(n) = Z^{-1}\{X(z)\}$, can be obtained by inverting each term in (3.4.27) and taking the corresponding linear combination. From Table 3.3 it follows that these terms can be inverted using the formula

$$Z^{-1} \left\{ \frac{1}{1 - p_k z^{-1}} \right\} = \begin{cases} (p_k)^n u(n), & \text{if ROC: } |z| > |p_k| \\ & \text{(causal signals)} \\ -(p_k)^n u(-n-1), & \text{if ROC: } |z| < |p_k| \\ & \text{(anticausal signals)} \end{cases} \quad (3.4.28)$$

If the signal $x(n)$ is causal, the ROC is $|z| > p_{\max}$, where $p_{\max} = \max\{|p_1|, |p_2|, \dots, |p_N|\}$. In this case all terms in (3.4.27) result in causal signal components and the signal $x(n)$ is given by

$$x(n) = (A_1 p_1^n + A_2 p_2^n + \dots + A_N p_N^n) u(n) \quad (3.4.29)$$

If all poles are real, (3.4.29) is the desired expression for the signal $x(n)$. Thus a causal signal, having a z-transform that contains real and distinct poles, is a linear combination of real exponential signals.

Suppose now that all poles are distinct but some of them are complex. In this case some of the terms in (3.4.27) result in complex exponential components. However, if the signal $x(n)$ is real, we should be able to reduce these terms into real components. If $x(n)$ is real, the polynomials appearing in $X(z)$ have real coefficients. In this case, as we have seen in Section 3.3, if p_k is a pole, its complex conjugate p_k^* is also a pole. As was demonstrated in Example 3.4.6, the corresponding coefficients in the partial-fraction expansion are also complex conjugates. Thus the contribution of two complex-conjugate poles is of the form

$$x_k(n) = [A_k (p_k)^n + A_k^* (p_k^*)^n] u(n) \quad (3.4.30)$$

These two terms can be combined to form a real signal component. First, we express A_k and p_k in polar form (i.e., amplitude and phase) as

$$A_k = |A_k| e^{j\alpha_k} \quad (3.4.31)$$

$$p_k = r_k e^{j\beta_k} \quad (3.4.32)$$

where α_k and β_k are the phase components of A_k and p_k . Substitution of these relations into (3.4.30) gives

$$x_k(n) = |A_k| r_k^n [e^{j(\beta_k n + \alpha_k)} + e^{-j(\beta_k n + \alpha_k)}] u(n)$$

or, equivalently,

$$x_k(n) = 2|A_k| r_k^n \cos(\beta_k n + \alpha_k) u(n) \quad (3.4.33)$$

Thus we conclude that

$$Z^{-1} \left(\frac{A_k}{1 - p_k z^{-1}} + \frac{A_k^*}{1 - p_k^* z^{-1}} \right) = 2|A_k| r_k^n \cos(\beta_k n + \alpha_k) u(n) \quad (3.4.34)$$

if the ROC is $|z| > |p_k| = r_k$.

From (3.4.34) we observe that each pair of complex-conjugate poles in the z-domain results in a causal sinusoidal signal component with an exponential envelope. The distance r_k of the pole from the origin determines the exponential weighting (growing if $r_k > 1$, decaying if $r_k < 1$, constant if $r_k = 1$). The angle of the poles with respect to the positive real axis provides the frequency of the sinusoidal signal. The zeros, or equivalently the numerator of the rational transform, affect only indirectly the amplitude and the phase of $x_k(n)$ through A_k .

In the case of *multiple* poles, either real or complex, the inverse transform of terms of the form $A/(z - p_k)^n$ is required. In the case of a double pole the

following transform pair (see Table 3.3) is quite useful:

$$Z^{-1} \left\{ \frac{pz^{-1}}{(1 - pz^{-1})^2} \right\} = np^n u(n) \quad (3.4.35)$$

provided that the ROC is $|z| > |p|$. The generalization to the case of poles with higher multiplicity is left as an exercise for the reader.

Example 3.4.8

Determine the inverse z-transform of

$$X(z) = \frac{1}{1 - 1.5z^{-1} + 0.5z^{-2}}$$

if

- (a) ROC: $|z| > 1$
- (b) **ROC:** $|z| < 0.5$
- (c) ROC: $0.5 < |z| < 1$

Solution This is the same problem that we treated in Example 3.4.2. The partial-fraction expansion for $X(z)$ was determined in Example 3.4.5. The partial-fraction expansion of $X(z)$ yields

$$X(z) = \frac{2}{1 - z^{-1}} - \frac{1}{1 - 0.5z^{-1}} \quad (3.4.36)$$

To invert $X(z)$ we should apply (3.4.28) for $p_1 = 1$ and $p_2 = 0.5$. However, this requires the specification of the corresponding ROC.

- (a) In case when the ROC is $|z| > 1$, the signal $x(n)$ is causal **and** both **terms** in (3.4.36) are causal terms. According to (3.4.28), we obtain

$$x(n) = 2(1)^n u(n) - (0.5)^n u(n) = (2 - 0.5^n) u(n) \quad (3.4.37)$$

which agrees with the result in Example 3.4.2(a).

- (b) When the ROC is $|z| < 0.5$, the signal $x(n)$ is anticausal. Thus both **terms** in (3.4.36) result in anticausal components. From (3.4.28) we obtain

$$x(n) = [-2^+ (0.5)^n] u(-n - 1) \quad (3.4.38)$$

- (c) In this case the **ROC** $0.5 < |z| < 1$ is a ring, **which** implies that the signal $x(n)$ is two-sided. Thus one of the terms corresponds to a causal signal and the other to an anticausal signal. Obviously, the given ROC is the overlapping of the regions $|z| > 0.5$ and $|z| < 1$. Hence the pole $p_2 = 0.5$ provides the causal part and the pole $p_1 = 1$ the anticausal. Thus

$$x(n) = -2(1)^n u(-n - 1) - (0.5)^n u(n) \quad (3.4.39)$$

Example 3.4.9

Determine the causal signal $x(n)$ whose z-transform is given by

$$X(z) = \frac{1 + z^{-1}}{1 - z^{-1} + 0.5z^{-2}}$$

Solution In Example 3.4.6 we have obtained the partial-fraction expansion as

$$X(z) = \frac{A_1}{1 - p_1 z^{-1}} + \frac{A_2}{1 - p_2 z^{-1}}$$

where

$$A_1 = A_2^* = \frac{1}{2} - j\frac{3}{2}$$

and

$$p_1 = p_2^* = \frac{1}{2} + j\frac{1}{2}$$

Since we have a pair of complex-conjugate poles, we should use (3.4.34). The polar forms of A_1 and p_1 are

$$A_1 = \frac{\sqrt{10}}{2} e^{-j71.565^\circ}$$

$$p_1 = \frac{1}{\sqrt{2}} e^{j\pi/4}$$

Hence

$$x(n) = \sqrt{10} \left(\frac{1}{\sqrt{2}} \right)^n \cos \left(\frac{\pi n}{4} - 71.565^\circ \right) u(n)$$

Example 3.4.10

Determine the causal signal $x(n]$ having the z -transform

$$X(z) = \frac{1}{(1+z^{-1})(1-z^{-1})^2}$$

Solution From Example 3.4.7 we have

$$X(z) = \frac{1}{4} \frac{1}{1+z^{-1}} + \frac{3}{4} \frac{1}{1-z^{-1}} + \frac{1}{2} \frac{z^{-1}}{(1-z^{-1})^2}$$

By applying the inverse transform relations in (3.4.28) and (3.4.35), we obtain

$$x(n) = \frac{1}{4}(-1)^n u(n) + \frac{3}{4}u(n) + \frac{1}{2}nu(n) = \left[\frac{1}{4}(-1)^n + \frac{3}{4} + \frac{n}{2} \right] u(n)$$

3.4.4 Decomposition of Rational z-Transforms

At this point it is appropriate to discuss some additional **issues** concerning the decomposition of rational z -transforms, which will prove very useful in the implementation of discrete-time systems.

Suppose that we have a rational z -transform $X(z)$ expressed as

$$X(z) = \frac{\sum_{k=0}^M b_k z^{-k}}{1 + \sum_{k=1}^N a_k z^{-k}} = b_0 \frac{\prod_{k=1}^M (1 - z_k z^{-1})}{\prod_{k=1}^N (1 - p_k z^{-1})} \quad (3.4.40)$$

where, for simplicity, we have assumed that $a_0 \equiv 1$. If $M \geq N$ [i.e., $X(z)$ is improper], we convert $X(z)$ to a sum of a polynomial and a proper function

$$X(z) = \sum_{k=0}^{M-N} c_k z^{-k} + X_{pr}(z) \quad (3.4.41)$$

If the poles of $X_{pr}(z)$ are distinct, it can be expanded in partial fractions as

$$X_{pr}(z) = A_1 \frac{1}{1 - p_1 z^{-1}} + A_2 \frac{1}{1 - p_2 z^{-1}} + \dots + A_N \frac{1}{1 - p_N z^{-1}} \quad (3.4.42)$$

As we have already observed, there may be some complex-conjugate pairs of poles in (3.4.42). Since we usually deal with real signals, we should avoid complex coefficients in our decomposition. This can be achieved by grouping and combining terms containing complex-conjugate poles, in the following way:

$$\begin{aligned} \frac{A}{1 - p z^{-1}} + \frac{A^*}{1 - p^* z^{-1}} &= \frac{A - A p^* z^{-1} + A^* - A^* p z^{-1}}{1 - p z^{-1} - p^* z^{-1} + p p^* z^{-2}} \\ &= \frac{b_0 + b_1 z^{-1}}{1 + a_1 z^{-1} + a_2 z^{-2}} \end{aligned} \quad (3.4.43)$$

where

$$\begin{aligned} b_0 &= 2 \operatorname{Re}(A), & a_1 &= -2 \operatorname{Re}(p) \\ b_1 &= -2 \operatorname{Re}(A p^*), & a_2 &= |p|^2 \end{aligned} \quad (3.4.44)$$

are the desired coefficients. Obviously, any rational transform of the form (3.4.43) with coefficients given by (3.4.44), which is the case when $a_1^2 - 4a_2 < 0$, can be inverted using (3.4.34). By combining (3.4.41), (3.4.42), and (3.4.43) we obtain a partial-fraction expansion for the z-transform with **distinct** poles that contains real coefficients. The general **result** is

$$X(z) = \sum_{k=0}^{M-N} c_k z^{-k} + \sum_{k=1}^{K_1} \frac{b_k}{1 + a_k z^{-1}} + \sum_{k=1}^{K_2} \frac{b_{0k} + b_{1k} z^{-1}}{1 + a_{1k} z^{-1} + a_{2k} z^{-2}} \quad (3.4.45)$$

where $K_1 + 2K_2 = N$. Obviously, if $M = N$, the first term is just a constant, and when $M < N$, this **term** vanishes. When there are **also** multiple poles, some additional higher-order terms should be included in (3.4.45).

An alternative form is obtained by expressing $X(z)$ as a product of simple terms as in (3.4.40). However, the complex-conjugate poles and zeros should be combined to avoid complex coefficients in the decomposition. Such combinations result in second-order rational terms of the following form:

$$\frac{(1 - z_k z^{-1})(1 - z_k^* z^{-1})}{(1 - p_k z^{-1})(1 - p_k^* z^{-1})} = \frac{1 + b_{1k} z^{-1} + b_{2k} z^{-2}}{1 + a_{1k} z^{-1} + a_{2k} z^{-2}} \quad (3.4.46)$$

where

$$\begin{aligned} b_{1k} &= -2 \operatorname{Re}(z_k), & a_{1k} &= -2 \operatorname{Re}(p_k) \\ b_{2k} &= |z_k|^2, & a_{2k} &= |p_k|^2 \end{aligned} \quad (3.4.47)$$

Assuming for simplicity that $M = N$, we see that $X(z)$ can be decomposed in the following way:

$$X(z) = b_0 \prod_{k=1}^{K_1} \frac{1 + b_k z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2} \frac{1 + b_{1k} z^{-1} + b_{2k} z^{-2}}{1 + a_{1k} z^{-1} + a_{2k} z^{-2}} \quad (3.4.48)$$

where $N = K_1 + 2K_2$. We will return to these important forms in Chapters 7 and 8.

3.5 THE ONE-SIDED Z-TRANSFORM

The two-sided z-transform requires that the corresponding signals be specified for the entire time range $-\infty < n < \infty$. This requirement prevents its use for a very useful family of practical problems, namely the evaluation of the output of nonrelaxed systems. As we recall, these systems are described by difference equations with nonzero initial conditions. Since the input is applied at a finite time, say n_0 , both input and output signals are specified for $n \geq n_0$, but by no means are zero for $n < n_0$. Thus the two-sided z-transform cannot be used. In this section we develop the one-sided z-transform which can be used to solve difference equations with initial conditions.

3.5.1 Definition and Properties

The **one-sided** or unilateral z-transform of a signal $x(n)$ is defined by

$$X^+(z) \equiv \sum_{n=0}^{\infty} x(n)z^{-n} \quad (3.5.1)$$

We also use the notations $Z^+\{x(n)\}$ and

$$x(n) \xleftrightarrow{z^+} X^+(z)$$

The one-sided z-transform differs from the two-sided transform in the lower limit of the summation, which is always zero, whether or not the signal $x(n)$ is zero for $n < 0$ (i.e., causal). Due to this choice of lower limit, the one-sided z-transform has the following characteristics:

1. It does not contain information about the signal $x(n)$ for negative values of time (i.e., for $n < 0$).
2. It is **unique** only for causal signals, because only these signals are zero for $n < 0$.
3. The one-sided z-transform $X^+(z)$ of $x(n)$ is identical to the two-sided z-transform of the signal $x(n)u(n)$. Since $x(n)u(n)$ is causal, the ROC of its transform, and hence the ROC of $X^+(z)$, is always the exterior of a circle. **Thus** when we deal with one-sided z-transforms, it is not necessary to refer to their ROC.

Example 3.1

Determine the one-sided z-transform of the signals in Example 3.1.1.

Solution From the definition (3.5.1), we obtain

$$x_1(n) = \{1, 2, 5, 7, 0, 1\} \xleftrightarrow{z^+} X_1^+(z) = 1 + 2z^{-1} + 5z^{-2} + 7z^{-3} + z^{-5}$$

$$x_2(n) = \{1, 2, 5, 7, 0, 1\} \xleftrightarrow{z^+} X_2^+(z) = 5 + 7z^{-1} + z^{-3}$$

$$x_3(n) = \{0, 0, 1, 2, 5, 7, 0, 1\} \xleftrightarrow{z^+} X_3^+(z) = z^{-2} + 2z^{-3} + 5z^{-4} + 7z^{-5} + z^{-7}$$

$$x_4(n) = \{2, 4, 5, 7, 0, 1\} \xleftrightarrow{z^+} X_4^+(z) = 5 + 7z^{-1} + z^{-3}$$

$$x_5(n) = \delta(n) \xleftrightarrow{z^+} X_5^+(z) = 1$$

$$x(n) = \delta(n-k), \quad k > 0 \xleftrightarrow{z^+} X_6^+(z) = z^{-k}$$

$$x_7(n) = \delta(n+k), \quad k > 0 \xleftrightarrow{z^+} X_7^+(z) = 0$$

Note that for a noncausal signal, the one-sided z-transform is not unique. Indeed, $X_2^+(z) = X_4^+(z)$ but $x_2(n) \neq x_4(n)$. Also for anticausal signals, $X^+(z)$ is always zero.

Almost all properties we have studied for the two-sided z-transform carry over to the one-sided z-transform with the exception of the *shifting* property.

Shifting Property

Case 1: Time Delay If

$$x(n) \xleftrightarrow{z^+} X^+(z)$$

then

$$x(n-k) \xleftrightarrow{z^+} z^{-k} [X^+(z) + \sum_{n=1}^k x(-n)z^n] \quad k > 0 \quad (3.5.2)$$

In case $x(n)$ is causal, then

$$x(n-k) \xleftrightarrow{z^+} z^{-k} X^+(z) \quad (3.5.3)$$

Proof. From the definition (3.5.1) we have

$$\begin{aligned} Z^+ \{x(n-k)\} &= z^{-k} \left[\sum_{l=-k}^{-1} x(l)z^{-l} + \sum_{l=0}^{\infty} x(l)z^{-l} \right] \\ &= z^{-k} \left[\sum_{l=-1}^{-k} x(l)z^{-l} + X^+(z) \right] \end{aligned}$$

By changing the index from l to $n = -l$, the result in (3.5.2) is easily obtained.

Example 352

Determine the one-sided z-transform of the signals

(a) $x(n) = a^n u(n)$

(b) $x_1(n) = x(n-2)$ where $x(n) = a^n$

Solution

(a) From (3.5.1) we easily obtain

$$X^+(z) = \frac{1}{1 - az^{-1}}$$

(b) We will apply the shifting property for $k = 2$. Indeed, we have

$$\begin{aligned} Z^+\{x(n-2)\} &= z^{-2}[X^+(z) + x(-1)z + x(-2)z^2] \\ &= z^{-2}X^+(z) + x(-1)z^{-1} + x(-2) \end{aligned}$$

Since $x(-1) = a^{-1}$, $x(-2) = a^{-2}$, we obtain

$$X_1^+(z) = \frac{z^{-2}}{1 - az^{-1}} + a^{-1}z^{-1} + a^{-2}$$

The meaning of the shifting property can be intuitively explained if we write (3.5.2) as follows:

$$\begin{aligned} Z^+\{x(n-k)\} &= [x(-k) + x(-k+1)z^{-1} + \dots + x(-1)z^{-k+1}] \\ &\quad + z^{-k}X^+(z) \quad k > 0 \end{aligned} \quad (3.5.4)$$

To obtain $x(n-k)$ ($k > 0$) from $x(n)$, we should shift $x(n)$ by k samples to the right. Then k "new" samples, $x(-k)$, $x(-k+1)$, $\dots$, $x(-1)$, enter the positive time axis with $x(-k)$ located at time zero. The first term in (3.5.4) stands for the z-transform of these samples. The "old" samples of $x(n-k)$ are the same as those of $x(n)$ simply shifted by k samples to the right. Their z-transform is obviously $z^{-k}X^+(z)$, which is the second term in (3.5.4).

Case 2: Time advance If

$$x(n) \xrightarrow{z^{-k}} X^+(z)$$

then

$$x(n+k) \xrightarrow{z^k} z^k \left[X^+(z) - \sum_{n=0}^{k-1} x(n)z^{-n} \right] \quad k > 0 \quad (3.5.5)$$

Proof. From (3.5.1) we have

$$Z^+\{x(n+k)\} = \sum_{n=0}^{\infty} x(n+k)z^{-n} = z^k \sum_{l=k}^{\infty} x(l)z^{-l}$$

where we have changed the index of summation from n to $l = n + k$. Now, from

(3.5.1) we obtain

$$X^+(z) = \sum_{l=0}^{\infty} x(l)z^{-l} = \sum_{l=0}^{k-1} x(l)z^{-l} + \sum_{l=k}^{\infty} x(l)z^{-l}$$

By combining the last two relations, we easily obtain (3.5.5).

Example 35.3

With $x(n)$, as given in Example 3.5.2, determine the **one-sided** z-transform of the signal

$$x_2(n) = x(n+2)$$

Solution We will apply the shifting theorem for $k=2$. From (3.5.5), with $k=2$, we obtain

$$Z^+\{x(n+2)\} = z^2 X^+(z) - x(0)z^2 - x(1)z$$

But $x(0)=1$, $x(1)=a$, and $X^+(z) = 1/(1-az^{-1})$. Thus

$$Z^+\{x(n+2)\} = \frac{z^2}{1-az^{-1}} - z^2 - az$$

The case of a time advance can be intuitively explained as follows. To obtain $x(n+k)$, $k > 0$, we should shift $x(n)$ by k samples to the left. As a result, the samples $x(0)$, $x(1)$, $\dots$, $x(k-1)$ "leave" the positive time axis. Thus we first remove their contribution to the $X^+(z)$, and then multiply what remains by z^k to compensate for the shifting of the signal by k samples.

The importance of the shifting property lies in its application to the solution of difference equations with constant coefficients and nonzero initial conditions. This makes the one-sided z-transform a very useful tool for the analysis of recursive linear time-invariant discrete-time systems.

An important theorem useful in the analysis of signals and systems is the final value theorem.

Final Value Theorem. If

$$x(n) \xleftrightarrow{z^+} X^+(z)$$

then

$$\lim_{n \rightarrow \infty} x(n) = \lim_{z \rightarrow 1} (z-1)X^+(z) \quad (3.5.6)$$

The limit in (3.5.6) exists if the **ROC** of $(z-1)X^+(z)$ includes the unit circle.

The proof of this theorem is left as an exercise for the reader.

This theorem is useful when we are interested in the asymptotic behavior of a signal $x(n)$ and we know its z-transform, but not the signal itself. In such cases, especially if it is complicated to invert $X^+(z)$, we can use the final value theorem to determine the limit of $x(n)$ as n goes to infinity.

Sec. 3.5 The One-sided z-Transform

Example 35.4

The impulse response of a relaxed linear time-invariant system is $h(n) = \alpha^n u(n)$, $|\alpha| < 1$. Determine the value of the step response of the system as $n \rightarrow \infty$.

Solution The step response of the system is

$$y(n) = h(n) * x(n)$$

where

$$x(n) = u(n)$$

Obviously, if we excite a causal system with a causal input the output will be causal. Since $h(n)$, $x(n)$, $y(n)$ are causal signals, the one-sided and two-sided z-transforms are identical. From the convolution property (3.2.17) we know that the z-transforms of $h(n)$ and $x(n)$ must be multiplied to yield the z-transform of the output. Thus

$$Y(z) = \frac{1}{1 - \alpha z^{-1}} \frac{1}{1 - z^{-1}} = \frac{z^2}{(z - 1)(z - \alpha)} \quad \text{ROC: } |z| > |\alpha|$$

Now

$$(z - 1) : \frac{z^2}{z - \alpha} \quad \text{ROC: } |z| > |\alpha|$$

Since $|\alpha| < 1$ the ROC of $(z - 1)Y(z)$ includes the unit circle* Consequently, we can apply (3.5.6) and obtain

$$\lim_{n \rightarrow \infty} y(n) = \lim_{z \rightarrow 1} \frac{z^2}{z - \alpha} = \frac{1}{1 - \alpha}$$

3.5.2 Solution of Difference Equations

The one-sided z-transform is a very efficient tool for the solution of difference equations with nonzero initial conditions. It achieves that by reducing the difference equation relating the two time-domain signals to an equivalent algebraic equation relating their one-sided z-transforms. This equation can be easily solved to obtain the transform of the desired signal. The signal in the time domain is obtained by inverting the resulting z-transform. We will illustrate this approach with two examples.

Example 35.5

The well-known Fibonacci sequence of integer numbers is obtained by computing each term as the sum of the two previous ones. The first few terms of the sequence are

$$1, 1, 2, 3, 5, 8, \dots$$

Determine a closed-form expression for the n th term of the Fibonacci sequence.

Solution Let $y(n)$ be the n th term of the Fibonacci sequence. Clearly, $y(n)$ satisfies the difference equation

$$y(n) = y(n - 1) + y(n - 2) \quad (3.5.7)$$

with initial conditions

$$y(0) = y(-1) + y(-2) = 1 \quad (3.5.8a)$$

$$y(1) = y(0) + y(-1) = 1 \quad (3.5.8b)$$

From (3.5.8b) we have $y(-1) = 0$. Then (3.5.8a) gives $y(-2) = 1$. Thus we have to determine $y(n)$, $n \geq 0$, which satisfies (3.5.7), with initial conditions $y(-1) = 0$ and $y(-2) = 1$.

By taking the one-sided z -transform of (3.5.7) and using the shifting property (3.5.2), we obtain

$$Y^+(z) = [z^{-1}Y^+(z) + y(-1)] + [z^{-2}Y^+(z) + y(-2) + y(-1)z^{-1}]$$

or

$$Y^+(z) = \frac{1}{1 - z^{-1} - z^{-2}} = \frac{z^2}{z^2 - z - 1} \quad (3.5.9)$$

where we have used the fact that $y(-1) = 0$ and $y(-2) = 1$.

We can invert $Y^+(z)$ by the partial-fraction expansion method. The poles of $Y^+(z)$ are

$$p_1 = \frac{1 + \sqrt{5}}{2} \quad p_2 = \frac{1 - \sqrt{5}}{2}$$

and the corresponding coefficients are $A_1 = p_1/\sqrt{5}$ and $A_2 = -p_2/\sqrt{5}$. Therefore,

$$y(n) = \left[\frac{1 + \sqrt{5}}{2\sqrt{5}} \left(\frac{1 + \sqrt{5}}{2} \right)^n - \frac{1 - \sqrt{5}}{2\sqrt{5}} \left(\frac{1 - \sqrt{5}}{2} \right)^n \right] u(n)$$

or, equivalently,

$$y(n) = \frac{1}{\sqrt{5}} \left(\frac{1}{2} \right)^{n+1} \left[\left(1 + \sqrt{5} \right)^{n+1} - \left(1 - \sqrt{5} \right)^{n+1} \right] u(n) \quad (3.5.10)$$

Example 3.5.6

Determine the step response of the system

$$y(n) = \alpha y(n-1) + x(n) \quad -1 < \alpha < 1 \quad (3.5.11)$$

when the initial condition is $y(-1) = 1$.

Solution By taking the one-sided z -transform of both sides of (3.5.11), we obtain

$$Y^+(z) = \alpha[z^{-1}Y^+(z) + y(-1)] + X^+(z)$$

Upon substitution for $y(-1)$ and $X^+(z)$ and solving for $Y^+(z)$, we obtain the result

$$Y^+(z) = \frac{\alpha}{1 - \alpha z^{-1}} + \frac{1}{(1 - \alpha z^{-1})(1 - z^{-1})} \quad (3.5.12)$$

By performing a partial-fraction expansion and inverse transforming the result, we have

$$\begin{aligned} y(n) &= \alpha^{n+1}u(n) + \frac{1 - \alpha^{n+1}}{1 - \alpha}u(n) \\ &= \frac{1}{1 - \alpha}(1 - \alpha^{n+2})u(n) \end{aligned} \quad (3.5.13)$$

3.6 ANALYSIS OF LINEAR TIME-INVARIANT SYSTEMS IN THE I-DOMAIN

In Section 3.4.3 we introduced the system function of a linear time-invariant system and related it to the unit sample response and to the difference equation description of systems. In this section we describe the use of the system function in the determination of the response of the system to some excitation signal. Furthermore, we extend this method of analysis to **nonrelaxed** systems. Our attention is focused on the important class of pole-zero systems represented by linear constant-coefficient difference equations with arbitrary initial conditions.

We also consider the topic of stability of linear **time-invariant** systems and describe a test for determining the stability of a system based on the coefficients of the denominator polynomial in the system function. Finally, we provide a detailed analysis of second-order systems, which form the basic building blocks in the realization of higher-order systems.

3.6.1 Response of Systems with Rational System Functions

Let us consider a pole-zero system described by the general linear **constant-coefficient** difference equation in (3.3.7) and the corresponding system function in (3.3.8). We represent $H(z)$ as a ratio of two polynomials $B(z)/A(z)$, where $B(z)$ is the numerator polynomial that contains the zeros of $H(z)$, and $A(z)$ is the denominator polynomial that determines the poles of $H(z)$. Furthermore, let us assume that the input signal $x(n)$ has a rational z-transform $X(z)$ of the form

$$X(z) = \frac{N(z)}{Q(z)} \quad (3.6.1)$$

This assumption is not overly restrictive, since, as indicated previously, most signals of practical interest have rational z-transforms.

If the system is initially relaxed, that is, the initial conditions for the difference equation are zero, $y(-1) = y(-2) = \dots = y(-N) = 0$, the **z-transform** of the output of the system has the form

$$Y(z) = H(z)X(z) = \frac{B(z)N(z)}{A(z)Q(z)} \quad (3.6.2)$$

Now suppose that the system contains simple poles $p_1, p_2, \dots, p_N$ and the z-transform of the input signal contains poles $q_1, q_2, \dots, q_L$, where $p_k \neq q_m$ for all $k = 1, 2, \dots, N$ and $m = 1, 2, \dots, L$. In addition, we assume that the zeros of the numerator polynomials $B(z)$ and $N(z)$ do not coincide with the poles $\{p_k\}$ and $\{q_k\}$, so that there is no pole-zero cancellation. Then a partial-fraction expansion of $Y(z)$ yields

$$Y(z) = \sum_{k=1}^N \frac{A_k}{1 - p_k z^{-1}} + \sum_{k=1}^L \frac{Q_k}{1 - q_k z^{-1}} \quad (3.6.3)$$

The inverse transform of $Y(z)$ yields the output signal from the system in the **form**

$$y(n) = \sum_{k=1}^N A_k(p_k)^n u(n) + \sum_{k=1}^L Q_k(q_k)^n u(n) \quad (3.6.4)$$

We observe that the output sequence $y(n)$ can be subdivided into two parts. The first part is a function of the **poles** $\{p_k\}$ of the system and is called the **natural** response of the system. The influence of the input signal on this part of the response is through the scale factors $\{A_k\}$. The second part of the response is a function of the poles $\{q_k\}$ of the input signal and is called the **forced** response of the system. The influence of the system on this response is exerted through the scale factors $\{Q_k\}$.

We should emphasize that the scale factors $\{A_k\}$ and $\{Q_k\}$ are functions of both sets of poles $\{p_k\}$ and $\{q_k\}$. For example, if $X(z) = 0$ so that the input is zero, then $Y(z) = 0$, and consequently, the output is zero. Clearly, then, the natural response of the system is zero. This implies **that** the natural response of the system is different from the zero-input response.

When $X(z)$ and $H(z)$ have one or more poles in common or when $X(z)$ and/or $H(z)$ contain multiple-order poles, then $Y(z)$ will have multiple-order poles. Consequently, the partial-fraction expansion of $Y(z)$ will contain factors of the **form** $1/(1 - p_l z^{-1})^k$, $k = 1, 2, \dots, m$, where m is the pole order. The inversion of these factors will produce **terms** of the **form** $n^{k-1} p_l^n$ in the output $y(n)$ of the system, as indicated in Section 3.4.2.

3.6.2 Response of Pole–Zero Systems with Nonzero Initial Conditions

Suppose that the signal $x(n)$ is applied to the pole–zero system at $n = 0$. Thus the signal $x(n)$ is assumed to be causal. The effects of **all** previous input signals to the system are reflected in the initial conditions $y(-1), y(-2), \dots, y(-N)$. Since the input $x(n)$ is causal and since we are interested in determining the output $y(n)$ for $n \geq 0$, we can use the one-sided z-transform, which allows us to deal with the initial conditions. Thus the one-sided z-transform of (3.4.7) becomes

$$Y^+(z) = - \sum_{k=1}^N a_k z^{-k} \left[Y^+(z) + \sum_{n=1}^k y(-n) z^n \right] + \sum_{k=0}^M b_k z^{-k} X^+(z) \quad (3.6.5)$$

Since $x(n)$ is causal, we can set $X^+(z) = X(z)$. In any case (3.6.5) may be expressed

$$\begin{aligned} Y^+(z) &= \frac{\sum_{k=0}^M b_k z^{-k}}{1 + \sum_{k=1}^N a_k z^{-k}} X(z) - \frac{\sum_{k=1}^N a_k z^{-k} \sum_{n=1}^k y(-n) z^n}{1 + \sum_{k=1}^N a_k z^{-k}} \\ &= H(z)X(z) + \frac{N_0(z)}{A(z)} \end{aligned} \quad (3.6.6)$$

Sec. 3.6 Analysis of Linear Time-Invariant Systems in the z-Domain

where

$$N_0(z) = - \sum_{k=1}^N a_k z^{-k} \sum_{n=1}^k y(-n) z^n \quad (3.6.7)$$

From (3.6.6) it is apparent that the output of the system with nonzero initial conditions can be subdivided into two parts. The first is the zero-state response of the system, defined in the z-domain as

$$Y_{zs}(z) = H(z)X(z) \quad (3.6.8)$$

The second component corresponds to the output resulting from the nonzero initial conditions. This output is the zero-input response of the system, which is defined in the z-domain as

$$Y_{zi}^+(z) = \frac{N_0(z)}{A(z)} \quad (3.6.9)$$

Hence the total response is the sum of these two output components, which can be expressed in the time domain by determining the inverse z-transforms of $Y_{zs}(z)$ and $Y_{zi}(z)$ separately, and then adding the results. Thus

$$y(n) = y_{zs}(n) + y_{zi}(n) \quad (3.6.10)$$

Since the denominator of $Y_{zi}^+(z)$, is $A(z)$, its poles are $p_1, p_2, \dots, p_N$. Consequently, the zero-input response has the form

$$y_{zi}(n) = \sum_{k=1}^N D_k (p_k)^n u(n) \quad (3.6.11)$$

This can be added to (3.6.4) and the terms involving the poles $\{p_k\}$ can be combined to yield the total response in the form

$$y(n) = \sum_{k=1}^N A'_k (p_k)^n u(n) + \sum_{k=1}^L Q_k (q_k)^n u(n) \quad (3.6.12)$$

where, by definition,

$$A'_k = A_k + D_k \quad (3.6.13)$$

This development indicates clearly that the effect of the initial conditions is to alter the natural response of the system through modification of the scale factors $\{A_k\}$. There are no new poles introduced by the nonzero initial conditions. Furthermore, there is no effect on the forced response of the system. These important points are reinforced in the following example.

Example 361

Determine the unit step response of the system described by the difference equation

$$y(n) = 0.9y(n-1) - 0.81y(n-2) + x(n)$$

under the following initial conditions:

(a) $y(-1) = y(-2) = 0$

(b) $y(-1) = y(-2) = 1$

Solution The system function is

$$H(z) = \frac{1}{1 - 0.9z^{-1} + 0.81z^{-2}}$$

This system has two complex-conjugate poles at

$$p_1 = 0.9e^{j\pi/3} \quad p_2 = 0.9e^{-j\pi/3}$$

The z-transform of the unit step sequence is

$$X(z) = \frac{1}{1 - z^{-1}}$$

Therefore,

$$\begin{aligned} Y_{zs}(z) &= \frac{1}{(1 - 0.9e^{j\pi/3}z^{-1})(1 - 0.9e^{-j\pi/3}z^{-1})(1 - z^{-1})} \\ &= \frac{0.542 - j0.049}{1 - 0.9e^{j\pi/3}z^{-1}} + \frac{0.542 + j0.049}{1 - 0.9e^{-j\pi/3}z^{-1}} + \frac{1.099}{1 - z^{-1}} \end{aligned}$$

and hence the zero-state response is

$$y_{zs}(n) = \left[1.099 + 1.088(0.9)^n \cos\left(\frac{\pi}{3}n - 5.2^\circ\right) \right] u(n)$$

(a) Since the initial conditions are zero in this case, we conclude that $y(n) = y_{zs}(n)$.

(b) For the initial conditions $y(-1) = y(-2) = 1$, the additional component in the z-transform is

$$\begin{aligned} Y_{zi}(z) &= \frac{N_0(z)}{A(z)} = \frac{0.09 - 0.81z^{-1}}{1 - 0.9z^{-1} + 0.81z^{-2}} \\ &= \frac{0.026 + j0.4936}{1 - 0.9e^{j\pi/3}z^{-1}} + \frac{0.026 - j0.4936}{1 - 0.9e^{-j\pi/3}z^{-1}} \end{aligned}$$

Consequently, the zero-input response is

$$y_{zi}(n) = 0.988(0.9)^n \cos\left(\frac{\pi}{3}n + 87^\circ\right) u(n)$$

In this case the total response has the z-transform

$$\begin{aligned} Y(z) &= Y_{zs}(z) + Y_{zi}(z) \\ &= \frac{1.099}{1 - z^{-1}} + \frac{0.568 + j0.445}{1 - 0.9e^{j\pi/3}z^{-1}} + \frac{0.568 - j0.445}{1 - 0.9e^{-j\pi/3}z^{-1}} \end{aligned}$$

The inverse transform yields the total response in the form

$$y(n) = 1.099u(n) + 1.44(0.9)^n \cos\left(\frac{\pi}{3}n + 38^\circ\right) u(n)$$

3.6.3 Transient and Steady-State Responses

As we have seen from our previous discussion, the response of a system to a given input can be separated into two components, the natural response and the forced

response. The natural response of a causal system has the form

$$y_{nr}(n) = \sum_{k=1}^N A_k (p_k)^n u(n) \quad (3.6.14)$$

where $\{p_k\}$, $k = 1, 2, \dots, N$ are the poles of the system and $\{A_k\}$ are scale factors that depend on the initial conditions and on the characteristics of the input sequence.

If $|p_k| < 1$ for all k , then, $y_{nr}(n)$ decays to zero as n approaches infinity. In such a case we refer to the natural response of the system as the **transient response**. The rate at which $y_{nr}(n)$ decays toward zero depends on the magnitude of the pole positions. If all the poles have small magnitudes, the decay is very rapid. On the other hand, if one or more poles are located near the unit circle, the corresponding terms in $y_{nr}(n)$ will decay slowly toward zero and the transient will persist for a relatively long time.

The forced response of the system has the form

$$y_{fr}(n) = \sum_{k=1}^L Q_k (q_k)^n u(n) \quad (3.6.15)$$

where $\{q_k\}$, $k = 1, 2, \dots, L$ are the poles in the forcing function and $\{Q_k\}$ are scale factors that depend on the input sequence and on the characteristics of the system. If all the poles of the input signal fall inside the unit circle, $y_{fr}(n)$ will decay toward zero as n approaches infinity, just as in the case of the natural response. This should not be surprising since the input signal is also a transient signal. On the other hand, when the causal input signal is a sinusoid, the poles **fall** on the unit circle and consequently, the forced response is also a sinusoid that persists for all $n \geq 0$. In this case, the forced response is called the **steady-state response** of the system. Thus, for the system to sustain a steady-state output for $n \geq 0$, the input signal must persist for all $n \geq 0$.

The following example illustrates the presence of the steady-state response.

Example 3.6.2

Determine the transient and steady-state responses of the system characterized by the difference equation

$$y(n) = 0.5y(n-1) + x(n)$$

when the input signal is $x(n) = 10 \cos(\pi n/4)u(n)$. The system is initially at rest (i.e., it is relaxed).

Solution The system function for this system is

$$H(z) = \frac{1}{1 - 0.5z^{-1}}$$

and therefore the system has a pole at $z = 0.5$. The z-transform of the input signal is (from Table 3.3)

$$X(z) = \frac{10(1 - (1/\sqrt{2})z^{-1})}{1 - \sqrt{2}z^{-1} + z^{-2}}$$

Consequently,

$$\begin{aligned} Y(z) &= H(z)X(z) \\ &= \frac{10(1 - (1/\sqrt{2})z^{-1})}{(1 - 0.5z^{-1})(1 - e^{j\pi/4}z^{-1})(1 - e^{-j\pi/4}z^{-1})} \\ &= \frac{6.3}{1 - 0.5z^{-1}} + \frac{6.78e^{-j28.7}}{1 - e^{j\pi/4}z^{-1}} + \frac{6.78e^{j28.7}}{1 - e^{-j\pi/4}z^{-1}} \end{aligned}$$

The natural or transient response is

$$y_{nr}(n) = 6.3(0.5)^n u(n)$$

and the forced or steady-state response is

$$\begin{aligned} y_{fr}(n) &= [6.78e^{-j28.7}(e^{j\pi/4}) + 6.78e^{j28.7}e^{-j\pi/4}]u(n) \\ &= 13.56 \cos\left(\frac{\pi}{4}n - 28.7^\circ\right)u(n) \end{aligned}$$

Thus we see that the steady-state response persists for all $n \geq 0$, just as the input signal persists for all $n \geq 0$.

3.6.4 Causality and Stability

As defined previously, a causal linear time-invariant system is one whose unit sample response $h(n)$ satisfies the condition

$$h(n) = 0 \quad n < 0$$

We have also shown that the ROC of the z -transform of a causal sequence is the exterior of a circle. Consequently, a linear time-invariant system is causal if and only if the ROC of the system function is the exterior of a circle of radius $r < \infty$, including the point $z = \infty$.

The stability of a linear time-invariant system can also be expressed in terms of the characteristics of the system function. As we recall from our previous discussion, a necessary and sufficient condition for a linear time-invariant system to be BIBO stable is

$$\sum_{n=-\infty}^{\infty} |h(n)| < \infty$$

In turn, this condition implies that $H(z)$ must contain the unit circle within its ROC.

Indeed, since

$$H(z) = \sum_{n=-\infty}^{\infty} h(n)z^{-n}$$

it follows that

$$|H(z)| \leq \sum_{n=-\infty}^{\infty} |h(n)z^{-n}| = \sum_{n=-\infty}^{\infty} |h(n)||z|^{-n}$$

When evaluated on the unit circle (i.e., $|z| = 1$),

$$|H(z)| \leq \sum_{n=-\infty}^{\infty} |h(n)|$$

Hence, if the system is **BIBO** stable, the unit circle is contained in the ROC of $H(z)$. The converse is also true. Therefore, a **linear time-invariant system is BIBO stable if and only if the ROC of the system function includes the unit circle**.

We should stress, however, that the conditions for causality and stability are different and that one does not imply the other. For example, a causal system may be stable or unstable, just as a noncausal system may be stable or unstable. Similarly, an unstable system may be either causal or noncausal, just as a stable system may be causal or noncausal.

For a causal system, however, the condition on stability can be narrowed to some extent. Indeed, a causal system is characterized by a system function $H(z)$ having as a ROC the exterior of some circle of radius r . For a stable system, the ROC must include the unit circle. Consequently, a causal and stable system must have a system function that converges for $|z| > r < 1$. Since the ROC cannot contain any poles of $H(z)$, it follows that a **causal linear time-invariant system is BIBO stable if and only if all the poles of $H(z)$ are inside the unit circle**.

Example 3.63

A linear time-invariant system is characterized by the system function

$$\begin{aligned} H(z) &= \frac{3 - 4z^{-1}}{1 - 3.5z^{-1} + 1.5z^{-2}} \\ &= \frac{1}{1 - \frac{1}{2}z^{-1}} + \frac{2}{1 - 3z^{-1}} \end{aligned}$$

Specify the ROC of $H(z)$ and determine $h(n)$ for the following conditions:

- (a) The system is stable.
- (b) The system is causal.
- (c) The system is anticausal.

Solution The system has poles at $z = \frac{1}{2}$ and $z = 3$.

- (a) Since the system is stable, its ROC must include the unit circle and hence it is $\frac{1}{2} < |z| < 3$. Consequently, $h(n)$ is noncausal and is given as

$$h(n) = \left(\frac{1}{2}\right)^n u(n) - 2(3)^n u(-n - 1)$$

- (b) Since the system is causal, its ROC is $|z| > 3$. In this case

$$h(n) = \left(\frac{1}{2}\right)^n u(n) + 2(3)^n u(n)$$

This system is unstable.

- (c) If the system is **anticausal**, its ROC is $|z| < 0.5$. Hence

$$h(n) = -\left[\left(\frac{1}{2}\right)^n + 2(3)^n\right] u(-n - 1)$$

In this case the system is unstable.

3.6.5 Pole–Zero Cancellations

When a z-transform has a pole that is at the same location as a zero, the pole is canceled by the zero and, consequently, the term containing that pole in the inverse z-transform vanishes. Such pole–zero cancellations are very important in the analysis of pole–zero systems.

Pole–zero cancellations can occur either in the system function itself or in the product of the system function with the z-transform of the input signal. In the first case we say that the order of the system is reduced by one. In the latter case we say that the pole of the system is suppressed by the zero in the input signal, or vice versa. Thus, by properly selecting the position of the zeros of the input signal, it is possible to suppress one or more system modes (pole factors) in the response of the system. Similarly, by proper selection of the zeros of the system function, it is possible to suppress one or more modes of the input signal from the response of the system.

When the zero is located very near the pole but not exactly at the same location, the term in the response has a very small amplitude. For example, nonexact pole–zero cancellations can occur in practice as a result of insufficient numerical precision used in representing the coefficients of the system. Consequently, one should not attempt to stabilize an inherently unstable system by placing a zero in the input signal at the location of the pole.

Example 364

Determine the unit sample response of the system characterized by the difference equation

$$y(n) = 2.5y(n-1) - y(n-2) + x(n) - 5x(n-1) + 6x(n-2)$$

Solution The system function is

$$\begin{aligned} H(z) &= \frac{1 - 5z^{-1} + 6z^{-2}}{1 - 2.5z^{-1} + z^{-2}} \\ &= \frac{1 - 5z^{-1} + 6z^{-2}}{(1 - \frac{1}{2}z^{-1})(1 - 2z^{-1})} \end{aligned}$$

This system has poles at $p_1 = 2$ and $p_2 = \frac{1}{2}$. Consequently, at first glance it appears that the unit sample response is

$$\begin{aligned} Y(z) = H(z)X(z) &= \frac{1 - 5z^{-1} + 6z^{-2}}{(1 - \frac{1}{2}z^{-1})(1 - 2z^{-1})} \\ &= z \left(\frac{A}{z - \frac{1}{2}} + \frac{B}{z - 2} \right) \end{aligned}$$

By evaluating the constants at $z = \frac{1}{2}$ and $z = 2$, we find that

$$A = \frac{5}{2} \quad B = 0$$

The fact that $B = 0$ indicates that there exists a zero at $z = 2$ which cancels the pole at $z = 2$. In fact, the zeros occur at $z = 2$ and $z = 3$. Consequently, $H(z)$

reduces to

$$\begin{aligned} H(z) &= \frac{1 - 3z^{-1}}{1 - \frac{1}{2}z^{-1}} = \frac{z - 3}{z - \frac{1}{2}} \\ &= 1 - \frac{2.5z^{-1}}{1 - \frac{1}{2}z^{-1}} \end{aligned}$$

and therefore

$$h(n) = \delta(n) - 2.5\left(\frac{1}{2}\right)^{n-1}u(n-1)$$

The reduced-order system obtained by canceling the common pole and zero is characterized by the difference equation

$$y(n) = \frac{1}{2}y(n-2) + x(n) - 3x(n-1)$$

Although the original system is also BIBO stable due to the pole-zero cancellation, in a practical implementation of this second-order system, we may encounter an instability due to imperfect cancellation of the pole and the zero.

Example 3.6.5

Determine the response of the system

$$y(n) = \frac{5}{6}y(n-1) - \frac{1}{6}y(n-2) + x(n)$$

to the input signal $x(n] = \delta(n) - \frac{1}{3}\delta(n-1)$.

Solution The system function is

$$\begin{aligned} H(z) &= \frac{1}{1 - \frac{5}{6}z^{-1} + \frac{1}{6}z^{-2}} \\ &= \frac{1}{\left(1 - \frac{1}{2}z^{-1}\right)\left(1 - \frac{1}{3}z^{-1}\right)} \end{aligned}$$

This system has two poles, one at $z = \frac{1}{2}$ and the other at $z = \frac{1}{3}$. The z-transform of the input signal is

$$X(z) = 1 - \frac{1}{3}z^{-1}$$

In this case the input signal contains a zero at $z = \frac{1}{3}$ which cancels the pole at $z = \frac{1}{3}$. Consequently,

$$\begin{aligned} Y(z) &= H(z)X(z) \\ Y(z) &= \frac{1}{1 - \frac{1}{2}z^{-1}} \end{aligned}$$

and hence the response of the system is

$$y(n) = \left(\frac{1}{2}\right)^n u(n)$$

Clearly, the mode $\left(\frac{1}{3}\right)^n$ is suppressed from the output as a result of the pole-zero cancellation.

3.6.6 Multiple-Order Poles and Stability

As we have observed, a necessary and sufficient condition for a causal linear *time*-invariant system to be BIBO stable is that all its poles lie inside the unit circle. The input signal is bounded if its z-transform contains poles $\{q_k\}$, $k = 1, 2, \dots, L$,

which satisfy the condition $|q_k| \leq 1$ for all k . We note that the forced response of the system, given in (3.6.15), is also bounded, even when the input signal contains one or more distinct poles on the unit circle.

In view of the fact that a bounded input signal may have poles on the unit circle, it might appear that a stable system may also have poles on the unit circle. This is not the case, however, since such a system produces an unbounded response when excited by an input signal that also has a pole at the same position on the unit circle. The following example illustrates this point.

Example 3.6.6

Determine the step response of the causal system described by the difference equation

$$y(n) = y(n-1) + x(n)$$

Solution The system function for the system is

$$H(z) = \frac{1}{1-z^{-1}}$$

We note that the system contains a pole on the unit circle at $z = 1$. The z -transform of the input signal $x(n) = u(n)$ is

$$X(z) = \frac{1}{1-z^{-1}}$$

which also contains a pole at $z = 1$. Hence the output signal has the transform

$$\begin{aligned} Y(z) &= H(z)X(z) \\ &= \frac{1}{(1-z^{-1})^2} \end{aligned}$$

which contains a double pole at $z = 1$.

The inverse z -transform of $Y(z)$ is

$$y(n) = (n+1)u(n)$$

which is a ramp sequence. Thus $y(n)$ is unbounded, even when the input is bounded. Consequently, the system is unstable.

Example 3.6.6 demonstrates clearly that BIBO stability requires that the system poles be strictly inside the unit circle. If the system poles are all inside the unit circle and the excitation sequence $x(n)$ contains one or more poles that coincide with the poles of the system, the output $Y(z)$ will contain multiple-order poles. As indicated previously, such multiple-order poles result in an output sequence that contains terms of the form

$$A_k n^b (p_k)^n u(n)$$

where $0 \leq b \leq m-1$ and m is the order of the pole. If $|p_k| < 1$, these terms decay to zero as n approaches infinity because the exponential factor $(p_k)^n$ dominates the term n^b . Consequently, no bounded input signal can produce an unbounded output signal if the system poles are **all** inside the unit circle.

Finally, we should state that the only useful systems which contain poles on the unit circle are the digital oscillators discussed in Chapter 4. We call such systems *marginally stable*.

3.6.7 The Schur-Cohn Stability Test

We have stated previously that the stability of a system is determined by the position of the poles. The poles of the system are the roots of the denominator polynomial of $H(z)$, namely,

$$A(z) = 1 + a_1 z^{-1} + a_2 z^{-2} + \cdots + a_N z^{-N} \quad (3.6.16)$$

When the system is causal all the roots of $A(z)$ must lie inside the unit circle for the system to be stable.

There are several computational procedures that aid us in determining if any of the roots of $A(z)$ lie outside the unit circle. These procedures are called **stability criteria**. Below we describe the Schur-Cohn test procedure for the stability of a system characterized by the system function $H(z) = B(z)/A(z)$.

Before we describe the Schur-Cohn test we need to establish some useful notation. We denote a polynomial of degree m by

$$A_m(z) = \sum_{k=0}^m a_k(z) z^{-k} \quad a_m(0) = 1 \quad (3.6.17)$$

The **reciprocal** or reverse **polynomial** $B_m(z)$ of degree m is defined as

$$\begin{aligned} B_m(z) &= z^{-m} A_m(z^{-1}) \\ &= \sum_{k=0}^m a_m(m-k) z^{-k} \end{aligned} \quad (3.6.18)$$

We observe that the coefficients of $B_m(z)$ are the **same** as those of $A_m(z)$, but in reverse order.

In the Schur-Cohn stability test, to determine if the polynomial $A(z)$ has all its roots inside the unit circle, we compute a set of coefficients, called **reflection coefficients**, $K_1, K_2, \dots, K_N$ from the polynomials $A, (z)$. First, we set

$$A_N(z) = A(z) \quad (3.6.19)$$

and

$$K_N = a_N(N)$$

Then we compute the lower-degree polynomials $A, (z), m = N-1, N-2, \dots, 1$, according to the recursive equation

$$A_{m-1}(z) = \frac{A_m(z) - K_m B_m(z)}{1 - K_m^2} \quad (3.6.20)$$

where the coefficients K_m are defined as

$$K_m = a_m(m) \quad (3.6.21)$$

The Schur–Cohn stability test states that *the polynomial $A(z)$ given by (3.6.16) has all its roots inside the unit circle if and only if the coefficients K_m satisfy the condition $|K_m| < 1$ for all $m = 1, 2, \dots, N$.*

We shall not provide a proof of the Schur–Cohn test at this point. The theoretical justification for this test is given in Chapter 11. We illustrate the computational procedure with the following example.

Example 3.6.7

Determine if the system having the system function

$$H(z) = \frac{1}{1 - \frac{2}{3}z^{-1} - \frac{1}{3}z^{-2}}$$

is stable.

Solution We begin with $A_2(z)$, which is defined as

$$A_2(z) = 1 - \frac{2}{3}z^{-1} - \frac{1}{3}z^{-2}$$

Hence

$$K_2 = -\frac{1}{3}$$

Now

$$B_2(z) = -\frac{1}{3} - \frac{2}{3}z^{-1} + z^{-2}$$

and

$$\begin{aligned} A_1(z) &= \frac{A_2(z) - K_2 B_2(z)}{1 - K_2^2} \\ &= 1 - \frac{2}{3}z^{-1} \end{aligned}$$

Therefore,

$$K_1 = -\frac{2}{3}$$

Since $|K_1| > 1$ it follows that the system is unstable. This fact is easily established in this example, since the denominator is easily factored to yield the two poles at $p_1 = -2$ and $p_2 = \frac{1}{2}$. However, for higher-degree polynomials, the Schur–Cohn test provides a simpler test for stability than direct factoring of $H(z)$.

The Schur–Cohn stability test can be easily programmed in a digital computer and it is very efficient in terms of arithmetic operations. Specifically, it requires only N^2 multiplications to determine the coefficients $\{K_m\}$, $m = 1, 2, \dots, N$. The recursive equation in (3.6.20) can be expressed in terms of the polynomial coefficients by expanding the polynomials in both sides of (3.6.20) and equating the coefficients corresponding to equal powers. Indeed, it is easily established that (3.6.20) is equivalent to the following algorithm: Set

$$a_N(k) = a_k \quad k = 1, 2, \dots, N \quad (3.6.22)$$

$$K_N = a_N(N) \quad (3.6.23)$$

Then, for $m = N, N-1, \dots, 1$, compute

$$K_m = a_m(m) \quad a_{m-1}(0) = 1$$

and

$$a_{m-1}(k) = \frac{a_m(k) - K_m b_m(k)}{1 - K_m^2} \quad k = 1, 2, \dots, m-1 \quad (3.6.24)$$

where

$$b_m(k) = a_m(m-k) \quad k = 0, 1, \dots, m \quad (3.6.25)$$

This recursive algorithm for the computation of the coefficients $\{K_m\}$ finds application in various signal processing problems, especially in speech signal processing.

3.6.8 Stability of Second-Order Systems

In this section we provide a detailed analysis of a system having two poles. As we shall see in Chapter 7, two-pole systems form the basic building blocks for the realization of higher-order systems.

Let us consider a causal two-pole system described by the second-order difference equation

$$y(n) = -a_1 y(n-1) - a_2 y(n-2) + b_0 x(n) \quad (3.6.26)$$

The system function is

$$\begin{aligned} H(z) &= \frac{Y(z)}{X(z)} = \frac{b_0}{1 + a_1 z^{-1} + a_2 z^{-2}} \\ &= \frac{b_0 z^2}{z^2 + a_1 z + a_2} \end{aligned} \quad (3.6.27)$$

This system has two zeros at the origin and poles at

$$p_1, p_2 = -\frac{a_1}{2} \pm \sqrt{\frac{a_1^2 - 4a_2}{4}} \quad (3.6.28)$$

The system is BIBO stable if the poles lie inside the unit circle, that is, if $|p_1| < 1$ and $|p_2| < 1$. These conditions can be related to the values of the coefficients a_1 and a_2 . In particular, the roots of a quadratic equation satisfy the relations

$$a_1 = -(p_1 + p_2) \quad (3.6.29)$$

$$a_2 = p_1 p_2 \quad (3.6.30)$$

From (3.6.29) and (3.6.30) we easily obtain the conditions that a_1 and a_2 must satisfy for stability. First, a_2 must satisfy the condition

$$|a_2| = |p_1 p_2| = |p_1| |p_2| < 1 \quad (3.6.31)$$

The condition for a_1 can be expressed as

$$|a_1| < 1 + a_2 \quad (3.6.32)$$

The conditions in (3.6.31) and (3.6.32) can also be derived from the Schur-Cohn stability test. From the recursive equations in (3.6.22) through (3.6.25), we find that

$$K_1 = \frac{a_1}{1 + a_2} \quad (3.6.33)$$

and

$$K_2 = a_2 \quad (3.6.34)$$

The system is stable if and only if $|K_1| < 1$ and $|K_2| < 1$. Consequently,

$$-1 < a_2 < 1$$

or equivalently $|a_2| < 1$, which agrees with (3.6.31). Also,

$$-1 < \frac{a_1}{1 + a_2} < 1$$

or, equivalently,

$$a_1 < 1 + a_2$$

$$a_1 > -1 - a_2$$

which are in agreement with (3.6.32). Therefore, a two-pole system is stable if and only if the coefficients a_1 and a_2 satisfy the conditions in (3.6.31) and (3.6.32).

The stability conditions given in (3.6.31) and (3.6.32), define a region in the coefficient plane (a_1, a_2) , which is in the form of a triangle, as shown in Fig. 3.15. The system is stable if and only if the point (a_1, a_2) lies inside the triangle, which we call the **stability triangle**.

The characteristics of the two-pole system depend on the location of the poles or, equivalently, on the location of the point (a_1, a_2) in the stability triangle. The poles of the system may be real or complex conjugate, depending on the value of the discriminant $A = a_1^2 - 4a_2$. The parabola $a_2 = a_1^2/4$ splits the stability

Figure 3.15 Region of stability (stability triangle) in the (a_1, a_2) coefficient plane for a second-order system.

triangle into two regions, as illustrated in Fig. 3.15. The region below the parabola ($a_1^2 > 4a_2$) corresponds to real and distinct poles. The points on the parabola ($a_1^2 = 4a_2$) result in real and equal (double) poles. Finally, the points above the parabola correspond to complex-conjugate poles.

Additional insight into the behavior of the system can be obtained from the unit sample responses for these three cases.

Real and distinct poles ($a_1^2 > 4a_2$). Since p_1, p_2 are real and $p_1 \neq p_2$, the system function can be expressed in the form

$$H(z) = \frac{A_1}{1 - p_1 z^{-1}} + \frac{A_2}{1 - p_2 z^{-1}} \quad (3.6.35)$$

where

$$A_1 = \frac{b_0 p_1}{p_1 - p_2} \quad A_2 = \frac{-b_0 p_2}{p_1 - p_2} \quad (3.6.36)$$

Consequently, the unit sample response is

$$h(n) = \frac{b_0}{p_1 - p_2} (p_1^{n+1} - p_2^{n+1}) u(n) \quad (3.6.37)$$

Therefore, the unit sample response is the difference of two decaying exponential sequences. Figure 3.16 illustrates a typical graph for $h(n)$ when the poles are distinct.

Real and equal poles ($a_1^2 = 4a_2$). In this case $p_1 = p_2 = p = -a_1/2$. The system function is

$$H(z) = \frac{b_0}{(1 - p z^{-1})^2} \quad (3.6.38)$$

and hence the unit sample response of the system is

$$h(n) = b_0(n+1)p^n u(n) \quad (3.6.39)$$

Figure 3.16 Plot of $h(n)$ given by (3.6.37) with $p_1 = 0.5$, $p_2 = 0.75$; $h(n) = [1/(p_1 - p_2)](p_1^{n+1} - p_2^{n+1})u(n)$.

Figure 3.17 Plot of $h(n)$ given by (3.6.39) with $p = \frac{3}{4}$: $h(n) = (n+1)p^n u(n)$

We observe that $h(n)$ is the product of a ramp sequence and a real decaying exponential sequence. The graph of $h(n)$ is shown in Fig. 3.17.

Complexconjugate poles ($a_1^2 < 4a_2$). Since the poles are complex conjugate, the system function can be factored and expressed as

$$H(z) = \frac{A}{1 - pz^{-1}} + \frac{A^*}{1 - p^*z^{-1}} \quad (3.6.40)$$

$$= \frac{A}{1 - re^{j\omega_0}z^{-1}} + \frac{A^*}{1 - re^{-j\omega_0}z^{-1}}$$

where $p = re^{j\omega_0}$ and $0 < \omega_0 < \pi$. Note that when the poles are complex conjugates, the parameters a_1 and a_2 are related to r and ω_0 according to

$$\begin{aligned} a_1 &= -2r \cos \omega_0 \\ a_2 &= r^2 \end{aligned} \quad (3.6.41)$$

The constant A in the partial-fraction expansion of $H(z)$ is easily shown to be

$$\begin{aligned} A &= \frac{b_0 p}{p - p^*} = \frac{b_0 r e^{j\omega_0}}{r(e^{j\omega_0} - e^{-j\omega_0})} \\ &= \frac{b_0 e^{j\omega_0}}{j2 \sin \omega_0} \end{aligned} \quad (3.6.42)$$

Consequently, the unit sample response of a system with complex-conjugate poles is

$$\begin{aligned} h(n) &= \frac{b_0 r^n}{\sin \omega_0} \frac{e^{j(n+1)\omega_0} - e^{-j(n+1)\omega_0}}{2j} u(n) \\ &= \frac{b_0 r^n}{\sin \omega_0} \sin(n+1)\omega_0 u(n) \end{aligned} \quad (3.6.43)$$

In this case $h(n)$ has an oscillatory behavior with an exponentially decaying envelope when $r < 1$. The angle ω_0 of the poles determines the frequency of oscillation and the distance r of the poles from the origin determines the rate of

Figure 3.18 Plot of $h(n)$ given by (3.6.43) with $b_0 = 1$, $\omega_0 = \pi/4$, $r = 0.9$;
 $h(n) = [b_0 r^n / (\sin \omega_0)] \sin[(n+1)\omega_0] u(n)$.

decay. When r is close to unity, the decay is slow. When r is close to the origin, the decay is fast. A typical graph of $h(n)$ is illustrated in Fig. 3.18.

3.7 SUMMARY AND REFERENCES

The z -transform plays the same role in discrete-time signals and systems as the **Laplace** transform does in continuous-time signals and systems. In this chapter we derived the important properties of the z -transform, which are extremely useful in the analysis of discrete-time systems. Of particular importance is the convolution property, which transforms the **convolution** of two sequences into a product of their z -transforms.

In the context of LTI systems, the convolution property results in the product of the z -transform $X(z)$ of the input signal with the system function $H(z)$, where the latter is the z -transform of the unit sample response of the system. This relationship allows us to **determine** the output of an LTI system in response to an input with transform $X(z)$ by computing the product $Y(z) = H(z)X(z)$ and then determining the inverse z -transform of $Y(z)$ to obtain the output sequence $y(n)$.

We observed that many signals of practical interest have rational **z -transforms**. Moreover, LTI systems characterized by constant-coefficient linear difference

equations, also possess rational system functions. Consequently, in determining the inverse z -transform, we naturally emphasized the inversion of rational transforms. For such transforms, the partial-fraction expansion method is relatively easy to apply, in conjunction with the ROC, to determine the corresponding sequence in the time domain. The one-sided z -transform was introduced to solve for the response of causal systems excited by causal input signals with nonzero initial conditions.

Finally, we considered the characterization of LTI systems in the z -transform domain. In particular, we related the pole-zero locations of a system to its time-domain characteristics and restated the requirements for stability and causality of LTI systems in terms of the pole locations. We demonstrated that a causal system has a system function $H(z)$ with a ROC $|z| > r_1$, where $0 < r_1 \leq \infty$. In a stable and causal system, the poles of $H(z)$ lie inside the unit circle. On the other hand, if the system is noncausal, the condition for stability requires that the unit circle be contained in the ROC of $H(z)$. Hence a noncausal stable LTI system has a system function with poles both inside and outside the unit circle with an annular ROC that includes the unit circle. The Schur-Cohn test for the stability of a causal LTI system was described and the stability of second-order system was considered in some detail.

An excellent comprehensive treatment of the z -transform and its application to the analysis of LTI systems is given in the text by Jury (1964). The Schur-Cohn test for stability is treated in several texts. Our presentation was given in the context of reflection coefficients which are used in linear predictive coding of speech signals. The text by Markel and Gray (1976) is a good reference for the Schur-Cohn test and its application to speech signal processing.

PROBLEMS

3.1 Determine the z -transform of the following signals.

(a) $x(n) = \{3, 0, 0, 0, 0, 6, 1, -4\}$

(b)
$$x(n) = \begin{cases} (\frac{1}{2})^n, & n \geq 5 \\ 0, & n \leq 4 \end{cases}$$

3.2 Determine the z -transforms of the following signals and sketch the corresponding pole-zero patterns.

(a) $x(n) = (1 + n)u(n)$

(b) $x(n) = (a^n + a^{-n})u(n)$, a real

(c) $x(n) = (-1)^n 2^{-n} u(n)$

(d) $x(n) = (na^n \sin \omega_0 n)u(n)$

(e) $x(n) = (na^n \cos \omega_0 n)u(n)$

(f) $x(n) = Ar^n \cos(\omega_0 n + \phi)u(n)$, $0 < r < 1$

(g) $x(n) = \frac{1}{2}(n^2 + n)(\frac{1}{3})^{n-1}u(n-1)$

(h) $x(n) = (\frac{1}{2})^n [u(n) - u(n-10)]$

Chap. 3 Problems

3.3 Determine the z-transforms and sketch the **ROC** of the following signals.

$$(a) x_1(n) = \begin{cases} (\frac{1}{3})^n, & n \geq 0 \\ (\frac{1}{2})^{-n}, & n < 0 \end{cases}$$

$$(b) x_2(n) = \begin{cases} (\frac{1}{3})^n - 2^n, & n \geq 0 \\ 0, & n < 0 \end{cases}$$

$$(c) x_3(n) = x_1(n+4)$$

$$(d) x_4(n) = x_1(-n)$$

3.4 Determine the z-transform of the following signals.

$$(a) x(n) = n(-1)^n u(n)$$

$$(b) x(n) = n^2 u(n)$$

$$(c) x(n) = -na^n u(-n-1)$$

$$(d) x(n) = (-1)^n \left(\cos \frac{\pi}{3} n \right) u(n)$$

$$(e) x(n) = (-1)^n u(n)$$

$$(f) x(n) = \{1, 0, -1, 0, 1, -1, \dots\}$$

↑

3.5 Determine the regions of convergence of right-sided, left-sided, and finite-duration two-sided sequences.

3.6 Express the z-transform of

$$y(n) = \sum_{k=-\infty}^n x(k)$$

in terms of $X(z)$. [*Hint*: Find the difference $y(n) - y(n-1)$.]

3.7 Compute the convolution of the following signals by means of the z-transform.

$$x_1(n) = \begin{cases} (\frac{1}{3})^n, & n \geq 0 \\ (\frac{1}{2})^{-n}, & n < 0 \end{cases}$$

$$x_2(n) = (\frac{1}{2})^n u(n)$$

3.8 Use the convolution property to:

(a) Express the z-transform of

$$y(n) = \sum_{k=-\infty}^n x(k)$$

in terms of $X(z)$.

(b) Determine the z-transform of $x(n) = (n+1)u(n)$. [*Hint*: Show first that $x(n) = u(n) * u(n)$.]

3.9 The z-transform $X(z)$ of a real signal $x(n]$ includes a pair of **complex-conjugate** zeros and a pair of complex-conjugate poles. What happens to these pairs if we multiply $x(n]$ by $e^{j\omega_0 n}$? (*Hint*: Use the scaling theorem in the **z-domain**.)

3.10 Apply the final value theorem to determine $x(\infty)$ for the signal

$$x(n) = \begin{cases} 1, & \text{if } n \text{ is even} \\ 0, & \text{otherwise} \end{cases}$$

3.11 Using long division, determine the inverse z-transform of

$$X(z) = \frac{1 + 2z^{-1}}{1 - 2z^{-1} + z^{-2}}$$

if (a) $x(n]$ is causal and (b) $x(n]$ is anticausal.

3.12 Determine the causal signal $x(n]$ having the z-transform

$$X(z) = \frac{1}{(1 - 2z^{-1})(1 - z^{-1})^2}$$

3.13 Let $x(n]$ be a sequence with z-transform $X(z)$. Determine, in terms of $X(z)$, the z-transforms of the following signals.

$$(a) \quad x_1(n) = \begin{cases} x\left(\frac{n}{2}\right), & \text{if } n \text{ even} \\ 0, & \text{if } n \text{ odd} \end{cases}$$

$$(b) \quad x_2(n) = x(2n)$$

3.14 Determine the causal signal $x(n]$ if its z-transform $X(z)$ is given by:

$$(a) \quad X(z) = \frac{1 + 3z^{-1}}{1 + 3z^{-1} + 2z^{-2}}$$

$$(b) \quad X(z) = \frac{1}{1 - z^{-1} + \frac{1}{2}z^{-2}}$$

$$(c) \quad X(z) = \frac{-6 + z^{-7}}{z^{-6} + z^{-7}}$$

$$(d) \quad X(z) = \frac{1 + 2z^{-2}}{1 + z^{-2}}$$

$$(e) \quad X(z) = \frac{1}{4} \frac{1 + 6z^{-1} + z^{-2}}{(1 - 2z^{-1} + 2z^{-2})(1 - 0.5z^{-1})}$$

$$(f) \quad X(z) = \frac{2 - 1.5z^{-1}}{1 - 1.5z^{-1} + 0.5z^{-2}}$$

$$(g) \quad X(z) = \frac{1 + 2z^{-1} + z^{-2}}{1 + 4z^{-1} + 4z^{-2}}$$

(h) $X(z)$ is specified by a pole-zero pattern in Fig. P3.14. The constant $G = \frac{1}{4}$

$$(i) \quad X(z) = \frac{1 - \frac{1}{2}z^{-1}}{1 + \frac{1}{2}z^{-1}}$$

$$(j) \quad X(z) = \frac{1 - az^{-1}}{z^{-1} - a}$$

Figure P3.14

3.15 Determine all possible signals $x(n]$ associated with the z-transform

$$X(z) = \frac{5z^{-1}}{(1 - 2z^{-1})(3 - z^{-1})}$$

3.16 Determine the convolution of the following pairs of signals by means of the z-transform.

- (a) $x_1(n) = (\frac{1}{4})^n u(n-1)$, $x_2(n) = [1 + (\frac{1}{2})^n] u(n)$
 (b) $x_1(n) = u(n)$, $x_2(n) = \delta(n) + (\frac{1}{2})^n u(n)$
 (c) $x_1(n) = (\frac{1}{2})^n u(n)$, $x_2(n) = \cos \pi n u(n)$
 (d) $x_1(n) = nu(n)$, $x_2(n) = 2^n u(n-1)$

3.17 Prove the final value theorem for the one-sided z -transform.

3.18 If $X(z)$ is the z -transform of $x(n)$, show that:

- (a) $Z\{x^*(n)\} = X^*(z^*)$
 (b) $Z\{\text{Re}[x(n)]\} = \frac{1}{2}[X(z) + X^*(z^*)]$
 (c) $Z\{\text{Im}[x(n)]\} = \frac{1}{2j}[X(z) - X^*(z^*)]$
 (d) If

$$x_k(n) = \begin{cases} x\left(\frac{n}{k}\right), & \text{if } n/k \text{ integer} \\ 0, & \text{otherwise} \end{cases}$$

then

$$X_k(z) = X(z^k)$$

- (e) $Z\{e^{j\omega_0 n} x(n)\} = X(z e^{-j\omega_0})$

3.19 By first differentiating $X(z)$ and then using appropriate properties of the z -transform, determine $x(n)$ for the following transforms,

- (a) $X(z) = \log(1 - 2z)$, $|z| < \frac{1}{2}$
 (b) $X(z) = \log(1 - z^{-1})$, $|z| > \frac{1}{2}$

3.20 (a) Draw the pole-zero pattern for the signal

$$x_1(n) = (r^n \sin \omega_0 n) u(n) \quad 0 < r < 1$$

- (b) Compute the z -transform $X_2(z)$, which corresponds to the pole-zero pattern in part (a).
 (c) Compare $X_1(z)$ with $X_2(z)$. Are they identical? If not, indicate a method to derive $X_1(z)$ from the pole-zero pattern.

3.21 Show that the roots of a polynomial with real coefficients are real or form complex-conjugate pairs. The inverse is **not** true, in general.

3.22 Prove the convolution and correlation properties of the z -transform using only its definition.

3.23 Determine the signal $x(n)$ with z -transform

$$X(z) = e^z + e^{1/z} \quad |z| \neq 0$$

3.24 Determine, in closed form, the causal signals $x(n)$ whose z -transforms are given by:

- (a) $X(z) = \frac{1}{1 + 1.5z^{-1} - 0.5z^{-2}}$
 (b) $X(z) = \frac{1}{1 - 0.5z^{-1} + 0.6z^{-2}}$

Partially check your results by computing $x(0)$, $x(1)$, $x(2)$, and $x(\infty)$ by an alternative method.

3.25 Determine all possible signals that can have the following z -transforms.

- (a) $X(z) = \frac{1}{1 - 1.5z^{-1} + 0.5z^{-2}}$
 (b) $X(z) = \frac{1}{1 - \frac{1}{2}z^{-1} + \frac{1}{4}z^{-2}}$
